

This is a digital copy of a book that was preserved for generations on library shelves before it was carefully scanned by Google as part of a project to make the world's books discoverable online.

It has survived long enough for the copyright to expire and the book to enter the public domain. A public domain book is one that was never subject to copyright or whose legal copyright term has expired. Whether a book is in the public domain may vary country to country. Public domain books are our gateways to the past, representing a wealth of history, culture and knowledge that's often difficult to discover.

Marks, notations and other marginalia present in the original volume will appear in this file - a reminder of this book's long journey from the publisher to a library and finally to you.

#### Usage guidelines

Google is proud to partner with libraries to digitize public domain materials and make them widely accessible. Public domain books belong to the public and we are merely their custodians. Nevertheless, this work is expensive, so in order to keep providing this resource, we have taken steps to prevent abuse by commercial parties, including placing technical restrictions on automated querying.

We also ask that you:

- + Make non-commercial use of the files We designed Google Book Search for use by individuals, and we request that you use these files for personal, non-commercial purposes.
- + Refrain from automated querying Do not send automated queries of any sort to Google's system: If you are conducting research on machine translation, optical character recognition or other areas where access to a large amount of text is helpful, please contact us. We encourage the use of public domain materials for these purposes and may be able to help.
- + Maintain attribution The Google "watermark" you see on each file is essential for informing people about this project and helping them find additional materials through Google Book Search. Please do not remove it.
- + Keep it legal Whatever your use, remember that you are responsible for ensuring that what you are doing is legal. Do not assume that just because we believe a book is in the public domain for users in the United States, that the work is also in the public domain for users in other countries. Whether a book is still in copyright varies from country to country, and we can't offer guidance on whether any specific use of any specific book is allowed. Please do not assume that a book's appearance in Google Book Search means it can be used in any manner anywhere in the world. Copyright infringement liability can be quite severe.

#### About Google Book Search

Google's mission is to organize the world's information and to make it universally accessible and useful. Google Book Search helps readers discover the world's books while helping authors and publishers reach new audiences. You can search through the full text of this book on the web at http://books.google.com/

#### PRELIMINARY REPORT

Q2

#### EXPERIMENTS ON THE EVAPORATIVE POWER

AND

OTHER PROPERTIES

OF

## AMERICAN COALS.

NAVY YARD,

Washington, November 28, 1843.

Sin: I have the honor to report that the experiments on the evaporative power of different coals, which have, for some time past, been carried on at this place, were concluded on the 18th instant. The examination of the other properties of the same materials, by such practical tests as can be here applied, is rapidly approaching its termination. The chemical analyses of some of the varieties hitherto operated on are yet to be performed. The large mass of facts collected during this research, referring to numerous points, and all of which are important to a full comprehension of the subject, is undergoing the examination and comparison which will enable me to present, in a final report, the respective and comparative values of the several kinds of coal for the different purposes for which fuel is employed.

A few weeks must unavoidably elapse before all these materials can be reduced to the required form, and furnished with the necessary drawings and illustrations. In the mean time, I beg leave to offer in this preliminary report some general statements relative to the origin, purposes, extent, and character of the researches which have been undertaken, and the nature of the results to be deduced from them.

The inquiry, now nearly completed, was instituted by your immediate predecessor, the Hon. A. P. Upshur, primarily on account of the difficulty which had been experienced, and the complaints which had been made, relative to the qualities of the coals procured for the naval service. It had been found that articles furnished to the Government at full prices, did not answer the expectations of those concerned in their consumption. While paying the highest prices for fuel, the efficiency of our steam vessels was sometimes impaired by its inferior quality, and the large amount of its impurity. Some few experiments on the subject had previously been made under authority of naval officers, but with means and appliances little calculated to afford the desired information.

It was evident that while securing the primary object—that of increasing the efficiency of the navy—the investigation must inevitably exercise a salutary influence on other branches of public defence, and be more or less felt in many important national interests. The possession, by any country, of a resource so important as extensive deposites of mineral fuel, may be justly regarded as an object of pride and pleasure, not less than one of universal interest. In some countries of Europe, it is well known, all mines belong to the public domain, even when found under a soil which is private property. Hence they are developed with the best resources of science, managed under the authority of special laws, and husbanded with the greatest care, to prevent unnecessary deterioration and waste. ernment of the United States, though not possessing this direct interest of proprietorship in mines, has still such a stake in the value of their resources, and the prosperity of citizens more immediately concerned in making them available, that the least which could reasonably be expected of it, is, to aid in some measure in ascertaining their true value. The department accordingly issued, about the middle of April, 1842, a notice, inviting the proprietors of mines, and others interested in the mining and sale of coals, to forward to this place, at their own charge, samples of their respective materials—engaging, on its part, to cause the same to be fully and impartially tested.

The question of the value of coals for the purpose of generating steam is, of course, mainly dependent on their heating power; that is, on the weight of water which a given weight of coal, burned under a given evaporating vessel, can convert into steam, while undergoing combustion. But this is not the only circumstance requiring investigation, in order to decide

their value, even for the purpose of sea-going steamers.

The weight of a given bulk of each coal, in its merchantable condition; the manner in which it burns, whether with much or little flame; the amount and character of its combustible ingredients; its facility or difficulty of ignition; the perfection of the combustion, or the proportion of the whole amount consumed to that of the combustible matter placed upon the grate; the concentration or diffusibility of its heat; the proportion of humidity, and that of the sulphur which it may contain, with the consequent liability, under certain circumstances, to undergo spontaneous combustion—are all points requiring attentive consideration. In addition to these, we have the question of the manner in which each coal behaves when coming to the temperature of ignition; its tendency to retain its original form, the nature and extent of change when any occurs, whether by simply cracking and disintegrating into angular fragments, or by enlarging the bulk, rounding away and obliterating the angles, and yet not agglutinating mass to mass; or, finally, by wholly changing its form and consistence, swelling to a great degree, and cohering so as to form a nearly continuous roof, and thus impeding the passage of air through the ignited coal. In some cases the question of the amount of solid matter which accompanies the gaseous products of combustion in the state of smoke, becoming soot upon the flues of the apparatus in which the combustion is conducted, is one of great practical importance. Of these incidental questions, the amount and character of the incombustible ingredients of different coals is a point eminently deserving of notice. It indicates the deduction which must, in all cases, be made from the heating power of an equal weight of the coal, considered as pure combustible matter; it shows the extent and kind of labor requisite in

managing the fitmace; it warns us what to expect in regard to the durability of grate bars, and the adhesion of scoriæ to those important appendages of the furnace. All these subjects must necessarily engage the attention of engineers and furnace managers, and no little portion of the good or bad character in cosl may be considered to depend on these circumstances. The relation of the incombustible ingredients of coal to each other is often such as to render the mixture fusible at the temperature of ordinary furnaces, or at least to be, in a certain proportion, reduced to a pasty coherent mass upon the grate, impeding the passage of air, leaving another portion unvitrified, and capable of passing through the interstices between the bars. For different coals this proportion is very different, even when the combustion is conducted as far as practicable in the same manner, and with the same intensity of heat.

In fact, there is scarcely an aspect in which this subject can be viewed, which does not open points of inquiry and comparison of the greatest practical importance to the naval service. It is not, however, solely with reference to their evaporative power, or their use under steam boilers, that coals are of importance to the navy of the United States, and of all other maritime nations. The very introduction of steam machinery into the navy has largely augmented the amount of workmanship in metals demanded for that branch of service; and the substitution of iron for wood in the vessels themselves, is destined vastly to increase the demand for such varieties of fuel as are best adapted to the various metallurgic arts. It was, therefore, evidently proper, in directing the investigation of the subject of the evaporative power of coals, that the department should require (as it did) the researches to be extended to all their applications. By instituting inquiries intended primarily for its own use and benefit, the Navy Department will have incidentally rendered an equal service to many important branches of art in the country. By inviting, as above stated, the proprietors of mines to furnish their respective coals for trial, it afforded to the mining interest an opportunity of ascertaining the relative value of their own products, as compared with those of many other districts and of foreign countries, and especially of having the peculiar adaptedness of each to its specific object clearly designated.

While so large an amount of both labor and capital is embarked in the mining and transportation of coal, and so many branches of industry depend on it for the successful prosecution of their labors; while so much of domestic comfort and so much of national wealth are, even now, in the infency of our mining operations, made to rely on this material; and while steam navigation upon the ocean, and, eventually, that upon our internal waters, must all be performed by its aid, we are warranted in the assertion that few subjects of a practical nature are more deeply and immediately

interesting to the public.

In this view we are sustained by observing how essentially it has contributed to the power and influence of one of the most commercial nations of the world. The coal deposites of a small island, which would itself searcely cover one of the coal fields of the United States, have afforded the chief means of carrying her conquests to the remotest parts of the globe.

In this view of the value of coal formations, wherever they may exist, it was evidently important to decide, by direct and practical tests, the comparative usefulness of American and foreign coals, as well as the relative value of the former in their numerous varieties.

The point of greatest interest—the heating power of combustible bodies has, heretofore, been sought to be determined by several different methods. The standard proposed by Lavoisier, and adopted by other chemists, was, the weight of ice melted by the combustion, either in atmospheric air, or in pure oxygen gas, of a given weight of the combustible bedy. The heat becoming latent during the liquefaction had been previously ascertained. The scale of experiments conducted on this principle was not a practical one; small specimens do not always faithfully represent large masses; and, in addition to these objections, a portion of the ice liquefied was liable to be recongealed before leaving the apparatus, so that the weight of water collected was not in every case a true index of the heat imparted. Great discrepancies occurred in the results. By other experimenters, including Count Rumford, the mere rise of temperature in water has been employed as a standard of heating power. But the limited range of temperature to which the experiment is confined requires that either a large quantity of water, or but a small portion of fuel, should be employed. The results would also fail of eliciting some of the important characteristics of coal, which can be fully developed only after a continuous action of some hours, and the use of considerable quantities.

The standard adopted by Mr. Marcus Bull, who some years since gave to the world a valuable series of experiments on the heating power of wood and coal, was the length of time during which a given difference could be maintained between an interior apartment in which combustion was conducted, and an exterior one which was exposed to the cooling effect of the surrounding air, by the consumption of a given weight of each kind of fuel.

The experiments of Mr. Bull were, it is understood, generally limited to

a pound or two of each combustible.

The mining engineers of Cornwall, and other parts of Great Britain, have formerly used, as a measure of heating power, the weight of water which could be raised one foot high by the consumption of a given bulk of coal, when burned under steam boilers which supplied the pumping engines at their mines. This standard is evidently liable to the objection, that it complicates the question of the heating power of coals, with that of the mechanical structure of engines—the production of steam, with its mode of application; questions wholly distinct from each other, and requiring independent solutions.

The distinguished mining engineer, Berthier, of Paris, proposed the employment of the oxide of lead as a material from which to obtain oxygen to effect the combustion of different substances, and made the weight of lead reduced from the state of oxide, hy a given weight of each combustible, a standard of its heating power. The composition of the protoxide of lead, or litharge, is well known; and the method of Berthier takes it for granted that the heating power of combustibles is proportionate to the weight of oxygen absorbed. The weight of lead reduced thus becomes indirectly the

measure of heat developed.

The German and other European chemists have sought to attain a knowledge of the heating power of fuel by ascertaining the precise chemical composition of the combustible portion, and thence inferring the weight of oxygen which must enter into chemical combination with it during combustion. To supply the oxygen, they have had recourse to compounds which yield it readily and in sufficient abundance—such as the chlorate of potash, the peroxide of copper, and the chromate of lead; but, instead of col-

betting the potash, copper, or lead reduced, (which would be impracticable,) they collect and weigh the gaseous products of combustion—the water and carbonic acid; and, from the known composition of these, infer the weight of exygen absorbed, respectively, by the hydrogen and carbon of the fuel. This is, in reality, no other than the method of analysis so successfully applied of late years to discover the composition of organic substances, among which coal is undoubtedly to be ranked. The quantity employed in analyses of this kind seldom or never exceeds ten grains. None of the above-described methods appeared to fulfil the conditions required in a practical determination of the evaporative power of the several kinds of coal.

Preference was therefore given to that which had, to a limited extent, been employed by Mr. Fyfe, of Edinburgh; Mr. Schaufhautl, Messrs. Parkes and Manby, in England; and by Dr. Dana, Mr. Hayes, and Mr. Francis, in this country. This method consists in burning the coals under a steam boiler, so arranged and furnished with apparatus as to be capable of complete regulation. The water delivered to the boiler, and the coals supplied to the furnace, are determined both by weight and measure.

The supply of air, the rate of combustion, the pressure and temperature of steam, the proportion and character of the products of combustion, both fixed and volatile, whether left on the grate or passing through the flues, are subject to careful observation and experiment. Here, the standard by which we measure the heating power of different coals is the weight of water which a given weight of each can evaporate from the temperature of 212° Fahrenheit. This standard is probably as constant as any in nature.

.With experiments conducted on this principle, the practice of generating heat for steam navigation, and for many other useful purposes, will be found to correspond in all essential circumstances.

The number of samples of coal on which trials of evaporative power have been made, is forty-one.

Of these, nine were anthracites from Pennsylvania, viz:

Two from the Beaver Meadow mines, sent for trial by the Beaver Meadow Railroad and Coal Company; two from the same mines, procured by the department for use in the steamer Union; one from the Lehigh Coal and Navigation Company's mines, sent by that company; one from "Lackawanna," sent by the Delaware and Hudson Canal Company; one from "Peach Mountain," Schuylkill county, sent by the Delaware Coal Company of Philadelphia; one from Forest Improvement mines, Broad Mountain, Schuylkill county; and one from Lyken's Valley Coal Company, Dauphin county.

The mean weight per cubic foot of all these samples, taken in the state in which they came to hand, as determined by actually weighing and measuring the whole of each sample at the time it was burned, was found to be 53.505 pounds. They are all characterized by retaining their form while exposed to the heat of ignition, undergoing no proper intumescence while parting with the small portion of volatile matter which they contain, or only being cracked and disintegrated into angular fragments. Their flame is generally short, of a blue color, and consequently possesses but little illuminating power. The last-mentioned coal, however, (that from Lyken's Valley,) though possessing the principal features of anthracite, also retains more than the usual amount of volatile matter, gives a considerable quantity of luminous flame, burns with more freedom than the generable

antly of anthracites, and hence constitutes a proper link of transition to the next class, or that of the free-burning or semi-bituminous coals.

Of these, twelve samples have been tried for evaporative power, viz:

Six from the coal field in the neighborhood of Cumberland, in Maryland, embracing one from Atkinson's mines; one from Neff's mines; two from Easby's mine called "Coal-in-Store;" and one from a quantity of

"Cumberland coal," purchased for the use of the navy yard.

Also, six from Pennsylvania, embracing one from Karthaus, on the west branch of the Susquehanna; one from Cambria county, sent by J. Brotherline; one from Lycoming Creek, sent by A. McIntyre, from near Ralston, Lycoming county; one from Blossburg, Tioga county, sent by the Arbon Coal Company, J. W. Johnson, agent; one from Quin's Run, Clinton county, by McDonald & Hallenback; and one from Dauphin and Susquehanna

Coal Company, by Isaac Lea, Esq.

Of these coals, the mean weight per cubic foot in their marketable condition is 52.844 pounds. They generally ignite readily, burn with a flame of moderate length, produce considerable intumescence, and, with one or two exceptions, but little agglutination in coking. Their respective peculiar properties will be understood from the tables and explanations hereafter to be reported. The form of masses of these coals is, in some cases, partly preserved in the coke; but a rounding of the edges, and enlargement of bulk, clearly distinguish them from all the anthracites.

The next class of coals is that from the bituminous coal fields in the neighborhood of Richmond and Petersburg, in Virginia; of which eleven

samples were examined:

Of these, four were from the Midlothian mines, furnished by the Midlothian Coal Company; one from the same mines, procured for use in the navy yard; one from Crouch & Snead's mines, Henrico county; one from the Chesterfield Mining Company, Chesterfield county, (formerly "Blackheath pits;") one from the Creek Coal Company; one from the Deep Run mines of J. Barr, Esq.; one from Tippecanoe mines, near Petersburg, P. D. & F. D. Osborne & Co., agents; and one from the Clover Hill Company, near the same place.

The mean weight per cubic foot, of all these coals, was found to be 49.276 pounds. They burn with a long flame; swell considerably on being ignited; the masses cohere and form a coke, in which the original form of the coal is wholly lost. They correspond in many particulars, as in form, composition, and heating power, with the foreign bituminous coals; of

which six varieties were tried, viz:

One from Sidney, Nova Scotia, sent by the Cunard Coal Mining Company; one of Pictou coal, sent by the same; also, one sample of Scotch, one of Newcastle, one of Liverpool, and one of Pictou; all procured, by order of the department, from Messrs. Laing & Randolph, extensive dealers in coal at New York.

Of these foreign samples, the weight per cubic foot is, on an average, 49.845 pounds, corresponding very nearly with that of the Virginia coals of the preceding class. As all these coals are found more or less extensively in the markets of our Atlantic cities, it was deemed expedient to give them a full and faithful examination, as well as all the samples sent from the different mines in the United States. Being among the most celebrated varieties of coal known abroad, they often claim the attention of American as well as other purchasers; and being of well-established character, they

will serve as common terms of comparison between the American and such foreign varieties of coal as are not represented in this series.

The coals of the United States above named are, it will be observed, all from the eastern slope of the Allegany mountains. The two following are the only ones from the western coal region, or great Mississippi basin:

One sample from Cannelton, Indiana, about one hundred miles below Louisville, Kentucky—sent by James Boyd, Esq., of Boston; one sample from Hepp & Co., of New Orleans, Louisiana—locality not yet ascertained.

The mean weight of these two samples was found to be 47.23 pounds per cubic foot. They burn with extreme activity, giving a long flame, and

yield a light, friable coke.

Besides the above classes, one sample was received from Messrs. Deaton & Barr, of that singular and interesting material known as natural "coke," from a mine of recent exploration in Tuckahoe, Virginia. Its weight per cubic foot was found to be 46.66 pounds. Two mixtures of anthracite and bituminous coal, in certain proportions, and two species of coke, (one from the Midlothian coal of Virginia, and the other from Neff's Cumberland coal,) were also tried.

The mean weight per cubic foot, of these artificial cokes, was found to be 32.57 pounds.

The series of experiments on evaporation was terminated by a single trial of the effect of dry pine wood, of which a quantity had been used daily in heating up the apparatus and preparing it for the reception of coal.

On each sample of coal were made from one to six trials, according to the quantity furnished. The coal consumed in one trial never exceeded 1,567 pounds—this being the greatest quantity which the apparatus could receive in the period allotted to each experiment, including the time requisite for clearing out the residua, making the necessary adjustments, and preparing for a new trial. The total weight of coal consumed in the trials of evaporative power has been nearly 621 tons; and the weight used, on an average, 978 pounds per trial. This statement may be sufficient to indicate that the experiments have been made on a scale unobjectionable on the score of magnitude.

The experiments on evaporation were barely commenced in the autumn of 1842; but only so far prosecuted at that time, as to test the working of

the apparatus.

They were recommenced on the 5th of April, 1843, and were unremittingly prosecuted, as above stated, until the 18th of the present month. Including the trial of wood, the whole number of experiments occupied 144 days. On each day continuous observations were made during a period averaging from 12 to 14 hours, according to the requisitions of the experiment. In the mean time, trials were made on specimens of all the samples, to test the results of Berthier's plan, as compared with the practical method above described.

The extensive smith shops of this navy yard afforded the means of testing (whenever the amount and nature of the sample allowed) the character

of each coal for the working of iron.

As it is, however, generally very difficult, in ordinary smith's work, to establish a standard of effect for this application of coals, the observations must be mainly confined to the behaviour of the coal in burning; the kind of fire it will form, whether hollow or otherwise; the amount and quality

of the cinder it will leave, and its effect upon the iron to which it is

applied.

An attempt was made to institute in the chain-cable shop a standard of comparison for heating power between the several coals, by employing a given weight of each in making the links of a chain of given size. A part of these trials have just been completed, and no time has yet been allowed to institute comparisons; but it is believed they will generally confirm the results obtained by evaporation.

The several samples of coal have been, or will yet be, analyzed by the ordinary method of determining the relation of the moisture, sulphur, fixed

carbon, gaseous matter, and earthly residua.

A number of the samples have been subjected to trial by the organic

method already alluded to.

To give the entire amount of information which the research was intended to elicit, the tables of observations, with the accompanying notes and explanations, aided by the illustrations now in progress, will be found indispensable. As the labor of experimenting is not yet terminated, any attempt to give a precise designation of the rank of each sample might not

only fail of its object, but do considerable injustice.

I cannot conclude these remarks without expressing the high satisfaction which I have felt at the zeal, ability, and assiduity with which my principal assistant, Dr. Henry King, has seconded all my endeavors to render these researches worthy of the important subject to which they relate, and worthy alike of the acceptance of your department. To the other assistants and artisans employed in the labors of the experiments, a like tribute is due, for the intelligence and punctuality with which they fulfilled the duties severally assigned to them. To the successive commandants, (Captains B. Kennon and J. H. Aulick,) with the other officers of the yard, and to the principal engineer and machinists, justice also requires that I should express my acknowledgments, for affording the needed facilities for these experiments, and promptly seconding the views of the department, as expressed in the instructions given at the time of their commencement.

I am, sir, very respectfully, your obedient servant,

WALTER R. JOHNSON.

To the Hon. David Henshaw, Secretary of the Navy.

#### REPORT

OF

## THE SECRETARY OF THE NAVY,

COMMUNICATING

The result of a series of experiments on coal.

June 8, 1844.

Read, and referred to the Committee on Naval Affairs.

June 11, 1844.

Ordered to be printed, and that one thousand additional copies be furnished for the use of the Senate.

June 17, 1844.

Ten thousand additional copies ordered to be printed.

#### NAVY DEPARTMENT, June 6, 1844.

Sin: An act of Congress, approved September 11, 1841, "making appropriations for the purchase of naval ordnance and ordnance stores, and for other purposes," authorized the Secretary of the Navy to apply a part of the sum thereby appropriated to the purpose of making experiments in matters connected with the naval service and the national defence.

In virtue of this authority, Professor W. R. Johnson, of Philadelphia, was empowered to institute a series of experiments upon coal, on which duty he has been zealously engaged. The result of his labors is herewith communicated in a large manuscript volume, containing the report, accompanied with several sheets of drawings and tabular statements.

The large and growing interests which the United States possess in their vast coal mines, scarcely yet developed, and the numerous national and domestic uses to which the article of coal is applied, will justify the length of time necessarily consumed in making the experiments; and the information contained in this report, it is hoped, will be found to compensate for the outlay.

I have the honor to be, very respectfully, your most obedient servant.

J. Y. MASON.

Hon. W. P. MANGUM,

President of the Senate.

#### REPORT.

Washington, June 3, 1844.

To the Hon. John Y. Mason, Secretary of the Navy.

SIR: In a concise preliminary report, which, under date of November 28, 1843, I had the honor to submit to the department, I took occasion to offer some remarks on the necessity which had been found to exist for procuring, by experiment, exact information as to the adaptation of various coals to the purposes of steam navigation. I referred to the extensive influence which researches of this nature exercise on the general system of national defences, on the manufacturing, mining, and commercial interests, and on the prosperity and domestic economy of communities having at command the important resources of mineral fuel. I stated the origin and progress of the researches which had been undertaken; pointed out some of the general purposes, primary and incidental, to be effected by the inquiry; referred to the several methods by which experimenters had heretofore sought to determine the heating power of combustible bodies, and indicated the nature of the practical standard of evaporative power employed in these experiments. I then gave a classified list of the coals assayed, designating the general properties of each class, and the names of the parties\* furnishing each sample. The other methods, both practical and analytical, which were employed, in addition to the evaporative process, to determine the character of each coal, were also briefly enumerated.

Since the time of making that report, a considerable number of the coals have undergone the usual analytical processes; and all the residua of the furnace have been carefully examined, to ascertain the proportion of combustible matter which they contained. In order to present in the most concise form all the information which the experiments were designed to elicit, a tabular view of each has been prepared, faithfully indicating the mode of action of each sample, under the variations of treatment to which it was subjected. From a careful examination of the several tables pertaining to each sample, a series of deductions is obtained; and a separate table embraces, under appropriate heads, the results of each experiment, and the average of the whole for each variety of fuel.

A description indicating the origin, specifying the external characters

<sup>•</sup> A few inaccuracies occurred in giving the names of persons and companies forwarding the coals, which I would here correct:

<sup>1.</sup> One sample of Cumberland coal was sent by the New York and Maryland Mining Company, by order of William Young, Esq., president. This was accidentally omitted in the preliminary report.

<sup>2.</sup> The sample said to be from "Atkinson's mines," should have been from Atkinson of Templeman's mines.

<sup>3.</sup> The samples of Pictou and Sidney were sent by Mr. Cunard, agent for the General Mining Association of London.

<sup>4.</sup> The small sample sent by Hepp & Co., of New Orleans, was Pittsburg coal.

[ 386 ] 6

and internal constitution of each coal, with an account of such experiments as do not refer to evaporative action, has been prefixed to the several tabular statements above referred to. For each class of coals, a general synoptical table has been derived from the averages deduced in the manner just described. From these synopses, a still more general table has been prepared, embracing the whole series of coals tried, and indicating the various characters which are most important in a practical point of view.

From this general table are deduced several classifications, according to the rank which experiment assigns to each coal. Among the important properties, with reference to which these classifications are made, are the weight under a given volume of each kind of coal; the facility of ignition; the completeness of combustion; the evaporative power for given weights, and that for given bulks; the amount of waste matter from the furnace, and a separate arrangement for the proportion of vitrified cinder. All these properties may be combined in making up an estimate of the relative val-

ues of coal for the purposes of steam navigation.

A tabular view of the proportion and characters of the residua left, after burning the several coals, is annexed. A number of other tables, relative to distinct classes of observations, will be found described in their proper places. Among these, one relates to the velocity with which the gases, produced by combustion, traversed the flues and chimney; others mark the influence of admitting currents of air to mix with the combustible gases at the furnace bridge, and distinguish separately the economy in time from that of fuel, due to such an arrangement. But, perhaps, none of the tables will be found more instructive than that which relates to the composition and heat-absorbing power of the gases, drawn from the flues during the combustion of numerous varieties of coal.

This table serves to show how large a proportion of atmospheric air always passes unchanged through our ordinary furnaces; and more particularly does it show the variableness of that proportion under different circumstances of the combustion; and, what is of not less practical importance, it enables us to ascertain what proportion of the heat, actually developed by the combustion of fuel, is applicable to useful purposes in the generation of steam, and how much is inevitably wasted in getting rid of the products of combustion. It serves the further purpose of determining the relation between the constitution of coals and their effective heating power; a question of the greatest importance to all who are concerned either in the selection or the use of fuel.

The general arrangement which I have adopted in presenting the materials of this report, is, after a few remarks on the prevalent measures of coal, to explain the several kinds of apparatus used, either in the analyses or the evaporative tests of coal. The latter will be found to embrace a description of the furnace, with illustrative plans, sections, and elevations; the construction and setting of the boiler; the apparatus for supplying it with water; that for drying the coals; the steam gauge, with its application; the gauge to show the draught of the chimney; and the apparatus for testing the products of combustion.

Following the description of apparatus for ultimate analyses of coals, will be found some experiments to test the relative value of re-agents generally

employed in such analyses.

The order of arrangement in describing the coals follows nearly that of their freedom from volatile matter, and is substantially the same as was

laid down in my preliminary report. The anthracite class is made to embrace the samples of fuel of analogous properties—such as "natural coke," artificial coke, and mixtures composed of four parts of anthracite and one part of bituminous coal.

#### 1. Measures of coal.

The coal bushel in England was formerly "a metallic cylinder 19½ inches in diameter inside, and 7½ inches deep. In filling it, the coals were to be heaped six inches high in the middle, so that a line drawn from the apex to opposite sides of the bushel would be 11½ inches in each direction." This would give the contents of a bushel of coals equal to 2,725.4 cubic inches; while the bushel, imperial measure, of the same country, is 2,218.192 cubic inches; and one bushel, Winchester measure, is 2,150.42 cubic inches.

The chaldron of coals with "ingrain" measure 104,809.572 cubic inches; and without "ingrain" 99,809.64 cubic inches. The former would be 38.45 bushels, as measured in and on the cylinder above described, and the latter 32.95 such bushels. Eight chaldrons of coal in Newcastle, are equal to 15½ chaldrons in London. The chaldron in Newcastle weighs 53 cwt.; and, consequently, in London it weighs 27.35 cwt. The same authority which furnishes these data,† also apprizes us that 88 pounds of coal make a bushel.

From the data furnished in the course of the following research, it will be evident that wide diversities exist in the weights of given bulks of different kinds of coal, and consequently great uncertainty must arise from attempting to estimate, by bulk alone, the value of any species of this material. It was not, therefore, deemed expedient to introduce anything in relation to the bushel of coals, either in regard to weight or efficiency; but to reduce all measures to the standard of a cubic foot, in which measure the contents of the bunkers of a steam ship are readily ascertained.

# 2. General plan and arrangement of apparatus for testing the evaporative power of coals.

The apparatus employed for this purpose is represented in plate 11, figures 1, 2, and 3; the first being a side, the second a front, and the third a rear elevation.

In these, as well as in the several longitudinal and transverse sections, the same references are, as far as practicable, applied to the same objects. the lateral elevation (fig. 1) brings into view not only the brick work of the stack, containing, as seen by a dotted outline, the boiler B, the water tank W, the intermediate cistern or filling apparatus C, the two safety valves V and V', the drying apparatus K, the water gauge G, but also the small adjacent apartment, in which are placed the manometer or steam gauge M, connected with the boiler by the iron tube *l*; the barometer *b*, with its attached thermometer *i*; as also the gas drawing and analyzing apparatus placed in the same apartment, including the chloride of

<sup>\*</sup> See Treatise on Fossil Fuel, Collieries, and the Coal Trade: London, 1841—page 378. † Grier's Mechanic's Pocket Dictionary, page 335.

[ 386 ] 8

calcium tube n, the sulphuric acid and asbestos tube o, the potash tube p, the second chloride tube q, the receiving jar r, with the arrangement for counterpoising it in the mercurial bath, and the graduated jars s, s, each furnished with a stopcock, by means of which it can be brought into communication with the receiver r, in order to receive portions of the gas drawn from the chimney to be tested for oxygen and other materials. This view also exhibits the two gauge cocks c, c, the dampers d and d', of which the former is represented as open, and the latter closed. It also exhibits the connexion between the safety valve V, and the chimney into which the steam was discharged through a 3-inch tube E; and the thermometer, f, showing the temperature of steam in the boiler.

It shows, at u, the opening of the iron tube in which is inserted the thermometer for measuring the temperature of the air on arriving at the grate. The rear end of the boiler (fig. 3) is seen to be furnished with a large stopcock, H, for discharging its contents; and the steam drying apparatus has a tube, m, projecting through a partition, and discharging

into the open air the steam which has traversed that apparatus.

Three sets of steps are seen, of which the first leads from the pavement to the platform or flooring laid over the brick work covering the boiler; the second leads from the level of that platform up to the water cistern, W, enabling the observer to read the scale on the rod, v, and to note the temperature of the water by a thermometer kept suspended in the cistern; and the third, placed in the office where the manometer and barometer are situated, enabled the observer to read those instruments, which are necessarily at an elevation of 7 or 8 feet from the pavement; x, x, are small puppet valves, by means of which either steam or water is allowed to escape from the water gauge G.

The height of the chimney to the top of the brick work is 41 feet, and its interior is 18 inches square; or its cross section is 324 square inches. The sheet-iron addition is 22 feet and  $\frac{3}{4}$  of an inch in height, 22.9 inches

in diameter, and its cross section 412.5 square inches.

In fig. 2, plate 11, is seen a front elevation of the apparatus, omitting the manometer and the apparatus for the analysis of gases. The dotted circle B represents the outline and defines the position of the boiler. The two cast-iron plates k, k, close the apertures in the brick work, through which the interior flues are reached in order to be swept: w is a similar cover to the side flue at the left of the boiler; and w, a plate closing a sweep-hole leading into the chimney.

g, g', and h, show the situation of the winches by which the several stopcocks (having on fig. 1 the same references) are managed; l, shows a section of the tube leading to the manometer; O, is the air port through which the air to supply the furnace entered beneath the ash pit, to find its way to the vertical air chambers on the sides of the stack, thence beneath the back end of the main fire flue to the grate. Just within this port are seen the two small thermometers e, and e', the latter having its bulb extending below the scale, and covered with a moistened cloth. These two constitute the dew-point apparatus. At j, and j', are two openings for the insertion of thermometers, one into the lower, and the other into the upper flue, by which the gases found their way into the chimney.

d is the damper, with its enclosing cast-iron frame, by which the pas-

sage to the chimney from the two interior flues k, k, is cut off. The damper

d' being drawn, opens a passage to the side flues opposite to w.

Between the two plates k, k, is seen a section i of the tube through which the gases were drawn after having passed the two interior return flues; y, y, are the fire doors, and z, z, the ash-pit doors—all closed as when the furpace is in action. L is the small subsidiary furnace used to augment the draught of the chimney, its ash pit opening being shown in front at the bottom, and its damper partly raised at N. The water gauge G, is seen to be furnished with a scale which was divided into inches and parts, above and below its zero, or normal level. At its upper and lower extremities are likewise seen screw nuts n, n, by which a complete opening through the glass tube is obtained, allowing it to be readily cleaned and wiped out. The remaining letters on this figure have reference to objects corresponding with those on fig. 1. In both figures the safety valves are seen to be surmounted by spindles or rods of about 30 inches in height, traversing guides, and supporting circular leaden weights, each weight having a slot by which it can be placed on its support.

Fig. 3 is a rear view of the apparatus, showing the outline of the end of the boiler by the dotted circle B. The openings of the interior flues k, k, and the exterior ones w, w'', as well as that of the fire flue y', are also severally indicated by these letters. The drying apparatus K, and the discharging cock H, the steam pipe m, from the drying apparatus, are

referred to in the above description of fig. 1.

Fig. 4, plate 11, is a vertical cross section through the water tank W, the filling apparatus C, the boiler B, and the several air passages and flues. The two side chambers, by which the air finds its way from the front to the rear of the furnace, are indicated by s, s; its return to the front at the level of the ash pit is marked by z; the level at which the thermometer is placed to show the temperature of the air on arriving at the grate is marked by a, though the tube containing it would not be actually cut by the vertical section now referred to.

The thermometer, marking the temperature of the water in the cistern W, is shown at t; w and w'' are the exterior or side flues, and k, k, the interior return flues. One of the supporting pillars of brick (of which five were placed under the length of the boiler) is seen in the middle of the

flue y, y, which is the main fire flue beneath the boiler.

The two dotted lines, o, o, and n, n, mark the levels at which the hori-

zontal sections, figs. 2 and 3, plate 111, are respectively taken.

Plate III, fig. 1, represents a vertical longitudinal section through the axis of the boiler, and such of its appendages as lie in that vertical plane. The water tank, with its float, the filling apparatus, safety valves, water gauge, drying apparatus, thermometer in the steam, and pipes for the discharge of steam, are all indicated by the same letters which have been employed in describing them in preceding figures.

In addition, this section brings into view the air passage at the level of the ash pit z, towards which the current of warm air is represented by

the arrows to be flowing from rear to front.

It also shows the position of the grate G, and the air plate p, through which a part of the current of air is represented to be passing. It likewise shows the subsequent passage of the products of combustion beneath the boiler along the main fire flue y, in which the pillars of brick already mentioned are seen at q, q, q, q, q. The entrance of the gases into one of

the interior flues, k, is marked by one of the curved arrows; and its exit, on its way to the upper or side flue, by another. The position of this upper flue, where it crosses the rear end of the boiler, is seen at w.

At i is seen the manner in which the small iron tube (i) is inserted into the space opposite to the openings of the interior flues. This part of the apparatus is seen enlarged at i, where the enlargement at o is filled with asbestos. At the opposite end, the chloride of calcium tube, r, is united with i by the usual elastic juncture. At a is a cross section of the thermometer (a) and its containing tube. This section shows the main supports of the boiler to be the fire-door frame at the front, and a cross bar of

cast iron (u) near the rear of the furnace.

Fig. 2, plate 111, is a horizontal section taken a little above the level of the grate at the height indicated by the line o, o, fig. 4, plate 11, exhibiting the perforated air plate at the furnace bridge, with the closing plate p, the air passages s, s, with the indications of currents of air. The position of the wet and dry bulb thermometers in the opening O, beneath the hearth plate in front of the grate G, is indicated by the dotted figures e, e'. The progress of the air entering below the hearth at O, and soon after turning to the right and left through passages, indicated by the arrows g, g, g, into the chambers s, s, and thence passing in a united current first to the front beneath the floor of the fire flue, and then through the grate and above that floor, as denoted by the arrows g', g', g', is presented to view in this section. The dotted figure of the thermometer a is made to represent its position beneath the bottom of the flue g.

The interior of the chimney stack is seen at S, and the several brick

supports of the boiler at q, q, q, q, q.

Fig. 3, plate 111, is a horizontal section taken at the level of n, n, fig. 4, plate 11. Besides the boiler B, and its interior flues k, k, this section shows the upper portion of the air chambers s, s; the thermometer j, which marked the temperature of the gases escaping to the chimney; the openings w, w, w, w, w, w, by which the upper flues and the chimney were reached, and the complete circuit of the air in five different directions. This last purpose is accomplished by means of the different degrees of strength given to the lines of the arrows, and by the number of accents applied to the letters attached to them. Thus, the faintly dotted arrow g indicates the current as flowing beneath the fire flue to reach the grate; g', g', the same air returning along the main fire flue to the back end of the boiler; g'', g'', the divided current traversing the two interior flues; g''', the current as it passes from the two interior flues into the upper and exterior flues, which it is seen to traverse to its point of exit into the chimney S.

### 3. Of the boiler and its appurtenances.

The boiler employed in these experiments is cylindrical in form, 30 feet in length, 3½ feet in diameter, and having near its lower arch two interior return flues, each of 10 inches interior diameter. The heads are flat, of wrought iron, and are securely stayed to the upper shell by oblique bolts. The boiler is furnished with two safety valves loaded directly; that is, without the intervention of a lever. Each valve has a lower base about three inches in diameter, and, consequently, an area of about 7 square inches.\* Of these two valves, that represented at V, fig. 1, plate

<sup>\*</sup> The true value of the lower base of V was 6.975, and that of V' 7.163 square inches. The upper base of the former was 9.73; that of the latter, 9.62 square inches.

11, near the front end, is connected with a tube E, for the escape of steam

leading into the chimney, where its orifice is turned upwards.

The other valve, V', is connected with an escape tube leading to the copper drying apparatus K, (fig. 1, plate 111,) and thence passing horizontally through the side of the building into the open air.

At M, (fig. 1, plate 111,) is seen the man hole, affording admittance to

the interior of the boiler.

At Y is an iron tube, closed at bottom and open at top, to contain oil, and in which is placed the thermometer f, by which the temperature of the steam is ascertained.

At I is a wrought-iron pipe leading from the steam chamber to the manometer. A stopcock cuts off, when required, the communication between the boiler and the manometer.

At the furnace end of the boiler is the glass water gauge G, furnished with stopcocks to cut off, when necessary, its communication with the boiler.

The centre of the water gauge is 6 inches below the upper interior arch of the boiler.

Near the water gauge are placed two gauge cocks, c, c, (fig. 2, plate 11,) one above and the other below the level just referred to.

At its front end, the boiler rests on the cast-iron frame containing the fire and ash pit doors; and at the opposite end, on a strong cast-iron bar supported at its two ends in the side walls of the furnace. Besides these two principal supports, it has five supports of brick, 4 feet apart, resting on the cast-iron floor of the flue below, each of the size of a single brick laid flatwise on its side, and lengthwise in the longitudinal direction of the boiler. These supports, and other arrangements in regard to the setting of the boiler, will be understood by reference to the vertical longitudinal section, fig. 1; the plan fig. 2, plate III; and to the vertical cross section, fig. 4, plate  $\pi$ ; in all of which they are designated by q.

The arrangement of the several flues, and the directions pursued by the products of combustion, from the time of leaving the grate till they arrive at the base of the stack, will be also perceived on examining the same figures, together with the plan fig. 3, plate 111, taken at the level of the upper or external flues, by which the air eventually reached the stack.

It will be observed on the transverse vertical section, that the walls enclosing the furnace and boiler are double, containing between them air chambers, s, s, running the whole length of the boiler, and serving to convey the air from the front to the rear of the structure. Having passed along these two chambers in a divided current, and become warmed by the heat passing through the inner walls, which are 13 inches thick, it turned downward to the level of the ash pit, and came in a single current through the passage Z, (fig. 4, plate 11,) immediately beneath the main furnace flue y, until it arrived at the rear of the grate. Here it entered the fire, passing either wholly through the fuel on the bars, or, in part, through the "air plate" p, (figs. 1 and 2, plate 111.)

Having passed the grate, the air, with the products of combustion, first passes horizontally beneath the lower arch of the boiler to the rear, thence returns in a divided current through the two interior return flues, k, k, (fig. 4, plate 11,) to the front; after which, it either passes through the opening of the "lower damper," d, (plate 11, fig. 2,) into the chimney. or, when that is closed, and the "upper damper," d', is opened, it ascends [ 386 ] · 12

from the ends of the two return flues into the left-hand exterior flue w; passes along it, in a united current, once more to the rear of the boiler; crosses the end, still at the same level, and enters the right-hand exterior flue, which it traverses till it reaches the exit flue, by which it finally arrives at the chimney, s; entering the latter at a level only 14 inches higher than when it passed by the other exit flue through the lower damper.

From this description, it will be observed that the air which supplies the combustion passes first into a chamber beneath the ash pit, about 7 feet long, and 3 feet 3 inches wide, along the sides of which are several openings, by which it finds its way into the two longitudinal side chambers, 30 feet long, 6 feet high, and 9 inches wide, between the two side walls; and having arrived, by these, at the rear of the boiler, passes 25 feet beneath the flue, arriving at the centre of the grate after a course of 60.5 feet. Thence a course of 58.5 feet brings the products of combustion to the aperture through the passage, by the lower damper, into the chimney; and of 62.5 feet farther, or 121 feet from the centre of the grate, to the point where they finally quit the boiler by the exterior flue. The part of the lower arch of the boiler, exposed to the action of heat, is 130 square feet, and that of the two return flues is 1.57 square feet; so that when the combustion was conducted by allowing the products to make their exit through the lower passage, or after passing twice the length of the boiler, the heated surface was 287 square feet. The boiler surface exposed in the exterior flue, or second circuit, is 90.5 feet; making the entire surface, when the products traversed four times the length of the boiler, 377.5 square feet. The grate being 5 feet long, and 3 feet 3 inches wide, when at its full dimensions, its area was 16.25 square feet; and the ratio of the grate surface to the heated surface, when the combustion was carried on through the lower damper, was 1:17.66; when through the upper damper, making the circuit 121 feet long, this ratio was 1:23.23.

When the air-plate bridge was introduced, it covered 8 inches of the length of the grate, reducing its area to 14.07 square seet, and increasing.

the ratio of heated to grate surface to  $\frac{3775}{1407}$  = 26.83 to 1.

During a few trials the grate was still farther reduced in area by the introduction, at the front end next to the fire doors, of a plate of iron 3 feet 3 inches long, 11½ inches wide, and one-fourth of an inch thick. This is termed the "coking plate," and was used while burning some of the samples of bituminous coal, which were so fine that large portions were liable to pass through the grate. With this plate in place, and the air plate in its usual position, the size of the grate was reduced to 11.375 square feet, and the heated to the grate surface increased to  $\frac{3775}{11375} = 33.18$  to 1.

On one occasion, instead of contracting the area of the grate by means of the coking plate, it was diminished by placing a row of bricks flatwise along each side of the furnace, reducing the grate surface to 10.291 square feet, and the ratio of heated to grate surface to  $\frac{3775}{10331} = 36.68$  to 1.

The grate was, in general, about 9 inches at the front, and 10 inches at the back end, below the lower arch of the boiler. On one or two occasions, however, which are noted in the tables of experiments, it was varied a little from this distance; but as no advantage appeared to attend the change, it was restored to this, as the most convenient working distance for all the varieties of fuel employed.

The grate bars used were three-fourths of an inch thick, and the spaces between them half an inch wide. They were supported at the centre, as

well as at each end, by a cast-iron bar 2½ inches thick, and 4 inches deep. Hence, when the grate was at its full size, the total amount of air passages

through the grate was nearly 5\{\frac{1}{2}} square feet.

The interior capacity of the boiler was such as to contain, when filled to the centre of the gauge tube, or normal level of the experiments, with water of 66° temperature, 12,795 lbs. This is the result of an experiment made after clearing out and wiping dry the interior of the boiler, and refilling it through the measuring cistern. Of this quantity, 493 pounds were then withdrawn, leaving 12,302 pounds, filling the boiler to within 1.1 inch of the normal level. On subsequently heating this to 230°, the water in the gauge, after taking all due precaution to withdraw the cold water from the glass tube, and filling it with that which was hot, stood once more at the normal level. Hence the apparent expansion of water in iron by an addition of 164 degrees of heat, is equivalent to  $\frac{493}{12302} = 0.0407$ , or a little more than one twenty-fifth part of its bulk at 66.°\*

#### 4. Supply of water.

The supply of water to the boiler was effected by means of the apparatus and hand gears seen at c, fig. 1, plate ii. From the tank or cistern W, the upper stopcock g allowed the water to descend into the intermediate small iron cistern C. When this cistern was full, the opening of the cock hallowed the steam from the boiler to act on the upper surface of the water in C; the first cock g being then, of course, closed. The opening of a third cock g', at the bottom of the cistern C, now permitted the water to descend into the boiler, while its place became occupied by steam. On closing the cocks g' and h, and once more opening the upper cock g, water instantly followed, condensing the steam and occupying its place. The apparatus was then in a condition to repeat the supply whenever the exigencies of the boiler demanded. Whenever a set of observations was made, it was with the intermediate cistern C full.

The large tank W (which was 5 feet and ½ inch on one side of its base, 4 feet 11½ inches on the other, and 3½ feet deep) contained, when filled to its usual height, about 5,110 lbs. of water. A float board rested on the surface of the water, and carried a light wooden rod v, passing through two guides, (as seen in plate ii, fig. 1.) On this rod were marked the weights of water contained in the cistern at different heights. The graduation of this scale was effected by actually weighing into the cistern successive portions of 100 lbs. of water, and marking the point indicated on the rod

This great increase in the rate of expansion of water above the boiling point, being nearly 7½ times as great in the range of the last 7 degrees as in the first stage of 40°, may probably possess some interest beyond that which attaches to it as a means of correcting the results of certain observations taken during this research. The subject has not, to my knowledge, attracted much attention among experimenters. It will be remarked, that this rapid augmentation of the rate of dilatation of water in iron, is not prevented by the conversion, at the same time, of a considerable quantity of water into steam of a high density.

<sup>\*</sup>The observations made on the gradual rise of temperature, and the corresponding weights of water which it had taken to fill the boiler, as much as the expansion by heat now did, gave the following table:

**[ 386 ]** 14

by a fixed brass band attached to one of the guides. This weighing took place when the water was at a temperature of 58°. A careful re-examination of the same gauge, when the water weighed was at 66°, showed that within these limits no appreciable difference of measurement, due to difference of temperature in the water, could be found while filling in 2,500 lbs. of water. The expansion of the materials of the cistern in this part of the scale was, therefore, inferred to be equivalent to that of the water which it contained.

By the experiments of Count Rumford, the expansion of water between. the freezing point and the highest temperature at which water was delivered to the boiler in any of these trials, (say about 58°,) is only 7.65 parts. in 2,000, or 0.38 of one percent. The lowest temperature of water in the tank, which will be found recorded in any of the tables, is 40°; near which point it is known water is at its maximum density; and from which point to 60°, the expansion is also known to be no more than 0.00008 of the whole volume at the former temperature. Hence, for all temperatures below that at which the water was weighed into the cistern, and the float rod gauged, any error from the difference of temperature in water is absolutely insignificant. In order to bring the upper part of the scale to an experimental test, I partly filled the cistern with water at 40° temperature, until the gauge rod marked 3,700 lbs. To these were added successive carefully weighed portions of 50 lbs. each of water, at a mean temperature of 190°. After each addition, the temperature was ascertained; the water being first thoroughly mixed, to obtain a uniform temperature throughout.

After the tenth addition, the temperature was exactly 58°, and the gauge

marked accurately 4,200 lbs.

After the twentieth addition, the temperature stood at 72°, and the gauge marked 4,713 lbs., showing the expansion to be  $\frac{276}{66}$  of the whole, or 0.276 of one per cent.

After the thirtieth addition, the gauge marked 5,221 lbs., and the temperature had risen to 82°.25. Hence the dilatation had been very nearly

0.4 of one per cent.

From the series of experiments just referred to, a scale of co-efficients for correction was constructed, by which the apparent weight read upon the gauge rod is reduced to the real weight of water which passed into the boiler. But, as already seen, no correction of this kind is really needed, except when the temperature exceeded 66°.

The following table shows the average temperature of water in the cistern, with the proportion which the actual weight of water, in each case, bore to the apparent weight delivered to the boiler. After the computation of water to 1 of coal from initial temperature had been made, this correction was applied, and furnished the line numbered 40 in the tables of deductions, and styled "water to 1 of coal, corrected for temperature of water in cistern."

Table of co-efficients for correcting the weight of water delivered to the boiler ut different temperatures.

Temperature.	Ratio of actual to apparent weight of water.
<b>58°</b> ,	1.0000
<b>65</b> .	0.9985
70	0.9977
<b>7</b> 5	0.9969
80	0.9963
85	0.9957
90	0.9953

Small as is the correction required by the cause now under consideration, it has not been deemed expedient to omit the estimation of its efficiency in modifying the results.

#### 5. Drying apparatus connected with the steam boiler.

This apparatus had for its object the determination of the hygrometric character of the several coals; and from this the loss which each sustains in combustible matter and in useful effect, from evaporating water out of its own mass, instead of the steam boiler. It will readily be perceived that the weight of water in any species of fuel is far different in its influence from an equal weight of incombustible earthy residuum; for the latter merely detracts so much from the weight of the raw material, while the former is not only useless in regard to the production of heat, but absolutely absorbs both the latent and sensible heat of steam, and carries into the chimney not only as much heat as would accompany the same weight of vapor from the boiler, but also the sensible heat in excess above that of the steam, as indicated by the thermometer which marked the temperature of the escaping gases.\*

### 6. Of the manometer, or mercurial steam gauge.

This apparatus is seen at M, fig. 1, plate 11.

A cast-iron cup of a cylindrical form, half an inch thick, about 2 inches interior diameter, has a lid of the same material and thickness, accurately fitted by grinding to the upper rim, and kept in place by a pair of wrought iron stirrups passing under the bottom of the cup, and retained in close contact with the lid by set screws beneath the bottom. Through a hole

<sup>&</sup>quot;If the ratio of the moisture to the total weight of coal be r, and the ratio of the ashes be  $a_r$  then will the really combustible matter be represented by 1-a-r. And if l be the latent heat of vapor at 212°, t the temperature at which the fuel is supplied to the grate, and t' that at which the products of combustion leave the boiler, then l+(t'-t) will be the whole number of degrees of heat absorbed by the moisture of the fuel, and r(l+(t'-t)) will be the quantity of heat applied to it, and which is, of course, so much detracted from the useful effect applicable to the boiler. In the tables of deductions are given the amounts of water to 1 of combustible, from 212°. The weight of water to 1 of fuel, after deducting the ashes, is there calculated on the supposition that the water receives only latent heat. If w be the tabular weight of water to 1 of combustible, then lw=to the amount of heat supplied by one part of coal, including its moisture, but excluding the ashes. Hence the whole quantity of heat developed and applied to the production of vapor, by one part of the fuel, in burning, is lw(1-a)+r(l+(l'-l)); and lw(1-a)+lr+(l'-l) gives the quantity of heat from 1 of true combustible.

in the centre of the lid, passes a glass tube open at bottom, but hermetically sealed at top. It is firmly cemented into the lid, and descends nearly to the bottom of the cup, through the mercury therein contained. The cup is connected with the top of the boiler, near its front end, by the wrought-iron tube l, about 15 feet long. This tube traverses a board partition, constituting one side of a small separate apartment or office, which consequently insulates the manometer and other apparatus from all direct radiation from the furnace.

The cup rests on a wooden transverse support crossing the apartment. Attached to this is a frame supporting the scale, of boxwood, on which the graduations of the instrument are placed. On one side of the tube are marked on the scale the heights above the original level of mercury in the cup, expressed not in inches, but in parts of an atmosphere of 30 inches in height. On the other side is placed a set of divisions, commencing from the top of the tube, and representing equal portions of its interior capacity, or volumes of the air which it contains.

A thin sliding band of brass embraces the scale, and carries on its front a ring which encircles the tube, and, having its upper edge on a level with that of the band, serves to guide the eye in noting the level of mercury in the tube, and marking its correspondence with the two graduations just

referred to.

The total length of the tube is 32.25 inches. Its interior capacity was divided by filling it with successive equal weighed portions of mercury, and marking on the glass the volumes thus indicated.

The whole tube contained 10.9116 volumes; and when first inserted in its place, it was filled with air thoroughly dried at a temperature of 39°,

and when the barometer was at 30.03 inches.

As the temperature rose with the advance of the season, the expansion caused, in the intervals of experiments, three successive discharges of air, not withstanding the column of mercury in the cup, which was 1.127 inch above the lower extremity. The first escape took place after the first day's experimenting, and reduced the remaining bulk of air to 10.2433 volumes when under a pressure of 30 inches of mercury at 32°.

The second escape took place after 35 days, (that is, on the 27th of May,) and reduced the remaining volumes to 9.3038 at the same pressure

and temperature.

The third escape took place on the 16th of June, in consequence of a partial vacuum formed in the boiler, by admitting a large quantity of cold water, after having blown out its contents for the purpose of cleansing. This discharge reduced the remaining volumes to 4.1624 at the temperature of 32° and pressure of 30 inches. It placed the manometer beyond all danger of farther loss, and the bulk of air remained without variation to the end of the series of experiments.

Near the manometer, and at the same level, was suspended a barometer

of the ordinary construction.

The two instruments were about 12 feet above mean tide water. The barometer had a thermometer attached, which was regarded as indicating the temperature of the mercury and air of the manometer, as well as of the barometer itself.

As the iron conducting tube *l* was carried almost exactly on a level, or with a slight inclination only towards the manometer, from the curved

portion near the boiler, it contained no appreciable head of water which could sensibly affect the pressure in the latter.

The water within it remained cold, except for a short distance—say 2 or

3 feet of the portion near the boiler.

The manometer served not only to mark the variations of pressure of steam from one observation to another, but also to calculate the absolute pressures\* in atmospheres, as well as in pounds per square inch.

Since mercusy expands  $\frac{1}{9990}$ th part of its volume by 1° Fahrenheit, therefore will p'=p

 $\left(\frac{9990}{9990+(t-32)}\right)$ ; t being the temperature marked by the attached thermometer at the time of observation.

The mercury descended in the cup of the manometer one-hundredth part as much as it ascended in the tube. Hence if h be the height (in parts of an atmosphere) observed in that instrument, h+.01h will be the height above the existing level in the cup, and  $(h+.01h)\times \left(\frac{9990}{9990+(t-32)}\right)$  will be the height of the same column reduced to a temperature of  $32^{\circ}$ . This may be represented by h'.

When no steam was in the boiler, and its interior was open to the air, it is evident that the compressing force exerted on the air contained in the manometer was equivalent to the difference between p' and h'; or, in terms of the observed data, it is  $= p\left(\frac{9990}{9990+(t-32)}\right) - \left(\frac{h+.01h}{1}\right)$ 

 $\times \left(\frac{9990+(t-32)}{9990+(t-32)}\right)$ . This quantity, which represents the elastic force of the air within the manometer when unaffected by the pressure of steam, enables us to reduce the observed volumes of air to the bulk which they would possess under the pressure of an atmosphere of 30 inches of mercury at 32°.

1. Let the observed volume be called V. Then, as at the temperature t it will be greater than at  $32^{\circ}$ , its bulk at the latter temperature may be represented by V. From the generally received expansion of air by heat,  $V = V\left(\frac{480}{480 + (t-32)}\right)$ .

2. Having obtained the bulk and elasticity of the enclosed air at 32°, under its actual tension, we obtain, by the well-known law of Mariotte, its volume when reduced to the tension of one

atmosphere at the same temperature. Thus, 1: p'-h':: V': V'(p'-h').

The volume thus calculated for unity of pressure and a standard temperature, may be compared with the volume observed in the same mass of air when subjected to the pressure of steam; but it must first be corrected for temperature at the time of such observation. Thus, let t be the temperature of the attached thermometer, observed when the manometer is subjected to a pressure of steam; let H be the height of the column of mercury simultaneously observed, and v the volume of contained air at the same time; then the equivalent of H, corrected for depression of mercury in the cup, and reduced to a temperature of  $33^{\circ}$ , may be represented by H'. And by the same principle as above adopted,  $H' = (H+.01H) \times \left(\frac{9990}{9990+(t-32)}\right)$ .

By the law already cited,  $v' = v \left( \frac{480}{480 + (t-32)} \right)$ , where v' is the volume which the compressed air would have, if brought to 32°. The elasticities being inversely as the volumes, we have  $v': V': p'-h' \cdot V' \times \frac{p'-h'}{r_{*}}$ .

Adding to the last result the corrected height of the mercurial column H', we obtain  $V' \times \frac{p'-h'}{v'}$  +H' for the pressure of steam in atmospheres above a vacuum. Deducting unity, and multiplying by 14.768, (the weight in pounds avoirdupois of a column of mercury having a base of one square inch and a height of 30 inches at 32°,) we have the pressure of steam in pounds avoirdupois above one almosphere. Calling this pressure F, the formula takes the form—

 $F = 14.768 \times \left( (V \times \frac{p' - h'}{r'}) + H' - 1 \right).$ 

The following example may illustrate the application of the above formula, both to the finding

<sup>\*</sup> To effect this calculation, let p be the observed height of the barometer in parts of an atmosphere of 30 inches of mercury, and let p' be the equivalent weight or height of column of mercury, at  $32^{\circ}$ .

It has not been deemed necessary to calculate every observation separately, but only to give the mean pressure during the period of each day in which it was ascertained to have been nearly uniform.

The extreme sensibility and perfect security of the manometer as a measure of the pressure of steam in a high-pressure steam boiler, as proved by my own experiments both before and since the commencement of researches on coal, and as well under more than 200 pounds to the

of the volume of the included air reduced to the standard temperature and pressure, and to the

determination of the mean pressure of steam, in atmospheres and in pounds:

On the 28th of June, during an experiment on Beaver Meadow anthracite, the height of the mercurial column in the manometer, before raising steam, was .348 atmosphere, the corresponding volumes of air 7.08. The barometer stood exactly at 30 inches, and the attached thermore. eter at 79°; or, p = 1.0000, t = 32 = 47°: consequently,  $p' = \frac{9990}{9990 + 47} \times 1 = .99534 = the$ barometric pressure reduced to 32°. h = .348, and .01h = .00348; so that  $h' = (h + .01h) \times$  $\left(\frac{9990}{9990+1-32}\right) = .35148 \times \frac{9990}{10037} = .34984$  = the corrected height of mercury in manometer. Hence p'-h'=.99534 — .34984 — .64550 = the elasticity of the included air.

V is by observation 7.08. Hence  $V' = 7.08 \times \frac{480}{527} = 6.4485$  = the bulk under the same tension if reduced to 32°. From these data, 1:: 0.6455:: 6.4485: 4.1627 = the volume of included

air reduced to 32° and 30 inches, or unity of pressure.

During the progress of the experiment, the period of steady pressure lasted from 10 a. m. to 5.30 p. m., in which were made fifteen sets of observations. These give, for the mean temperature of the attached thermometer,  $81^{\circ} - T$ ; for the mean height, H = .5358; and for the mean volume of air, v = 5.213: consequently, T = 32 = 49, H + 01H = .54116, and  $H = .54116 \times$  $\frac{9990}{10039}$  - .53853 - the corrected height of mercury in manometer for this period. v' - 5 213  $\times \frac{480}{529}$  - 4.7301 - the volumes under the same pressure, had the temperature been 32°.

Again: as V'(p'-h') = 4.1627,  $\frac{V'(p'-h')}{r} = 4.1627 \div 4.7361$ , = .88902; to which adding H' = .53853, we obtain for the total pressure of steam above a vacuum, 1.41855 atmospheres. Deducting unity and multiplying by 14.768, we get 6.1812 pounds as the mean pressure above as

atmosphere during that day's operations.

It is to be observed that an opportunity was not every day afforded for verifying the true volume of air in the manometer. The boiler often contained, in the morning, steam of considerable tension from the preceding day's operations. By means, however, of verifications made on seventeen dif-Gerent days, after the 16th of June, it was ascertained that the calculations afforded a mean of 4.1625 the volumes of the remaining air under standard temperature and pressure. It will also be noted, that the expansion of air by 1° Fahrenheit increase of temperature, is assumed to be th of its bulk at 82°. This is the received determination of Gay Lussac, Dalton, and Crich-The more recent experiments of Rudberg, Magnus, and Regnault, concur in fixing it at about \_\_\_\_d part of the same bulk. A few of the observations in this research have been calculated according to both these bases, but it will be seen that the differences thence resulting are practically unimportant.

It is proper to state, that, in calculating the bulk of air in the manometer, no account has been taken of the expansions of the tube itself; the reason of which is, that the quantity would have been too minute to be recognised in the observations. By the mean of ten determinations, by different experimenters, of the expansion of glass by heat, its increase in volume by an augmentation of 180° of heat is equal to  $\frac{1}{894}$ th part of its bulk at 32°; and this for 1° is  $\frac{1}{70920}$ th part. The highest temperature observed in the attached thermometer was 96°. Hence the proportion of the whole apparent volume of air, which could have been affected by this cause of exar, must have been only  $\frac{96-32}{.70920} = \frac{1}{1108}$ th of its bulk at 32°; while, during the progress of the research, the observations took cognizance of no proportion less than  $\frac{1}{993}$ d part of the total volume; and for a great portion of the time it was but about five-ninths of this amount.

square inch, as at the very moderate pressures here employed, induce me to recommend its general adoption for steam vessels, as well as for stationary high-pressure steam boilers. For this purpose, it would probably be advisable to have the glass tube rise exactly 30 inches above the original level of mercury in the fountain. The volumes of air would then be measured in parts of an atmosphere, and would be, in every instance, the complement of the height of moreury observed.

As the manemeter can be placed at any required distance from the boiler, it may always be made convenient for the inspection of the superintendent, or officer in command; an advantage seldom possessed by the common safety valve, or other apparatus for indicating the pressure of

steana.

The barometer and thermometer being now regarded as indispensable to the navigator, will, of course, be constant accompaniments of the management.

## 7. Of the syphon, or water gauge, for indicating the draught of the chimney.

This apparatus is seen at u, fig. 2, plate m. It is composed of an inverted syphon of glass, with one end bent at right angles, to enter the chimney where the lower escape flue enters it. The other end is open to the external air. The first syphon used had an internal caliber of only 0.2 inch. Subsequently, however, another tube was substituted, having a bore of 0.45 inch in diameter. To the syphon was attached a scale divided into inches and tenths, for the purpose of observing the differences of level in the two limbs. The indications of this gauge represent the differences of pressure within and without the chimney, or the tendency of air to enter it. Water is about 837 times beavier than air; and, consequently, the numbers in the column of the tables headed "Height of water in syphon," multiplied by this number, give approximately the height of a column of air, which would balance the observed column of water. This is the head of pressure of air, under which air tended to enter the chimney in consequence of the rarefaction of the gases within, or the force of the jet of steam thrown into it from the boiler by the escape pipe E. Thus, when the difference of level in the two arms of the syphon was 0.3 inch, the head of pressure of air was  $0.3 \times 837 = 251.1$ inches, or 20.99 feet. It is evident, however, that, as the motion in the fixes is not that of cold air, but of air greatly rarefied, the same head of pressure will represent a far greater velocity than would be given by the same force to air of the mean density of the atmosphere. The drangit of the chimney was dependent on three or four distinct causes: 1. The elevated temperature and consequent attenuation of the gases. This was occasionally as high as 400°, but generally below 300°, as will be observed in column of "Gases entering the chimney." 2. The jet of steam from the boiler. The gauge was always found to rise when the steam came to escape after taking the weights from the front safety valve, so as to throw a jet into the chimney. 3. The heat of the small furnace L, figs. 1 and 2, plate 11. This furnace was used for some of the experiments with litharge, and was particularly beneficial in starting the fire, and giving a prompt action while heating up the boiler in the morning. 4. The prevalence of certain winds. Owing, probably, to the configura; ratus was placed, the prevalence of westerly or northwesterly winds was found to give a considerable augmentation to the force of draught. This is illustrated in table LXIX, in which, under the head of "remarks," it is stated that the wind was strong from the northwest, the syphon marked sometimes as high as .48 or .49 inch, while, on the four other days on which the same coal was burned, with the wind from other quarters, it seldom rose so high as .40 or .41 inch. It does not necessarily follow that the rate of combustion is proportioned to the mere force of draught as measured by the gauge. A variation in the thickness of the coal on the grate may present at one time far more obstruction to the passage of air than at another. The observations made by means of highly bituminous coal thrown suddenly on a bright mass of ignited coke, noting the time in which the smoke arrived at the top of the chimney, will serve to indicate the real velocity of current in the flues and chimney.

## 8. Time in which smoke reached the chimney top.

While the chimney was of the original height of 41 feet from the bottom, or 36 feet from the centre of the upper flue leading from the boiler, the trial of time occupied by the smoke in moving from the grate through the upper flue to the chimney top, on the 27th of May, gave as a mean result 21 seconds—the horizontal distance being 127 feet, and the vertical height 41 feet, or at the mean rate of 8 feet per second. The draught gauge stood on that day at a mean height, during steady action, of .2371 inch, and at a maximum of .25 inch.

After this trial, and previous to the 31st of May, the chimney was raised by the sheet-iron addition, 22 feet and \$\frac{2}{3}\$ of an inch. On that day, observations were again made on the rate of motion of smoke. It then took 15 seconds only for the smoke to perform the same circuits. The height of the draught gauge was then from .41 to .45 inch, or at a mean, during steady action, it was .4053; and the mean rate of motion was 12.66 feet per second—having now to travel 190 feet from the grate to the point of its final escape into the air.\*

\* The weight of a cubic foot of air at mean pressure and temperature is 523 grains; one cubic foot of water weighs 1,000 ounces avoirdupois; and mercury has a specific gravity of 13.568.

By this relation, it appears that air is but  $\frac{1}{837}$ th part as heavy as water; and if the air were of equaldensity throughout, it would have a height of 27,807 feet. Under a head of 27,807 feet of its own mass, air would flow into a vacuum with a velocity of 1,338 feet per second. As the homogeneous atmosphere is equivalent to 407.04 inches of water, the velocities under the following heights in the syphon ought to be as follows, according to the well-known law which governs the movement of fluids:

Height of water	in suphon.				Vel	ocity of A	ow.
.10 inc		•	•-	-	•	6.632	feet per second.
.15 4	•	•	•	•	•	8.122	¯ <b>66</b>

The table referred to in the text above, will furnish many opportunities of secretaining how mearly the calculated and the observed velocities approximate each other.

An extensive series of the observations made on this subject will be found at table CXCIII.

## 9. On the measure of heating power.

The practical measure of heating power, which I have adopted in the experiments mainly relied on in this research, and which, by way of distinction, is called evaporative power, is based on the known quantity of heat which water, raised to the boiling point, requires in order to convert it into steam.

This quantity I have taken to be 1,030° Fahrenheit, (5723 centigrade,)

according to my own determination made some years since.\*

It is obvious that, as all the varieties of fuel are referred to one and the same standard, it is not material to the justness of the comparison whether one determination or another of latent heat be adopted. I have preferred the one above mentioned, because I know exactly the means and precautions which were used in obtaining it.

# 10. Of the corrections required in applying the standard for determining the relative evaporating powers of different coals.

Having ascertained the number of pounds of water which have been supplied to the boiler during the continuance of the combustion of any known weight of coal, it might seem an easy problem to decide the evaporative power by dividing the former quantity by the latter.

Several circumstances, however, require to be considered, and their dis-

tinct effects computed, before we can arrive at a just conclusion.

- 1. The water delivered to the boiler was not always at the same temperature, and, consequently, different quantities of sensible heat were required to be added before it could begin to be converted into steam. The differences of temperature during the same day, and in the successive portions of water used in any one experiment, generally amounted to but a few degrees. But, in the course of nearly eight months, the extremes were 40 and 86°.
- 2. It frequently happened that the experiment was terminated by filling up the boiler with cold water after the fire had become extinct, and when, consequently, the temperature of the steam had fallen considerably below that due to the pressure generally maintained. In these cases, it is evident that the latter portions of the vaporization must have taken place from water already raised to the temperature of the steam itself, (generally about 230°,) instead of that of the water in the cistern, which was at some point within the limits above named. Hence it is necessary to calculate how much less water would have been evaporated, had the supplying of cold water continued till the heating power of the fuel was exhausted and the safety valve closed.
- 3. As the water supplied to the boiler at the conclusion of an experiment was cold, it often reduced the contents of the latter to a temperature below that at which the 0 on the water gauge had been adjusted; and, as it seldom happened that on two successive days the temperature of steam and water in the boiler at the beginning of experiment was exactly the

<sup>\*</sup> See Report on Strength of Materials for Steam Boilers.

[ 🗯 ]

order to know when the requisite weight had been added. For this purpose many sets of observations were made on the gradual heating of the water from different low temperatures up to the usual point at which evaporation was carried on. These series of observations enabled me to ascertain that the same weight of water was in the boiler at the end as at the beginning of an experiment. This subject has already been treated of, while speaking of the boiler. The correction for differences of temperature of water in the boiler was further facilitated by many observations on the rise of water in the gauge by given weights supplied from the cistern.\*

## 11. Apparatus for testing the products of combustion.

In order to form a tolerably correct judgment of the degree of perfection with which fuel is burned, and its available heat applied, it is necessary to study with attention the nature, condition, and proportions of the products of combustion. Among the solid products are soot, or finely divided carbon, carbonate of ammonia, and sulphate of ammonia; all of which may be occasionally found coating the flues and chimney in greater or less quantities, according to the nature of the coal, and the mode of effecting its combustion.

Among the principal gaseous products are watery vapor, carbonic acid, and nitrogen mixed with unchanged atmospheric air. Not only is it necessary to determine whether the combustible parts of the fael have been duly combined with oxygen of the air, and have thus produced their greatest heating effect, but also whether the air itself have found its way to the furnace in excess, and been heated at the expense of the fuel, without contributing anything to its useful effect.

In order to accomplish this purpose, the apparatus seen at n, o, p, q, r, A, Ag. 1, plate 11, and partly exhibited at i in the sectional fig. 1, plate 11, was devised. This consisted of a wrought-iron tube i, penetrating to the fine at the point where the gases made their exit from the two in-

Having obtained a common standard of comparison for measuring the heating power of a given weight of coal, including all its ingredients, the efficiency of a given bulk of the same, (as of a cubic foot,) is obtained by multiplying the weight of such bulk by the value of the expression just given. To derive from the same the heating power of the unit weight of combustible matter, we deduct the wastage per cent. from 100. If the ratio of incombustible matter be represented by a, the water to 1 of combustible matter in the coal will be obtained by the formula  $\frac{cw}{l(100-a)}$ 

The last expression is useful in determining the relative values of different samples of coal from the same coal field; in which it often happens that the proportion of incombustible ingredients is very variable, while the composition of the combustible portion is nearly constant.

<sup>\*</sup> Having obtained the weight of water to 1 of coal, from the initial temperature, this quantity may be called w; the mean temperature at which it was delivered to the boiler, derived from the column of "temperature of water in tank," may be called t; for this temperature a co-efficient, derived from the experiments already referred to on the gradual heating of the water in the cistern, is applied, and may be represented by c; the corrected weight of water to 1 of coal will then be expressed by cw; the mean gain of sensible heat by the water in coming to the boiling point, will be expressed by  $212^{\circ}-t$ . Let l be the latent heat of steam, which, by my own determination, (see Report on Strength of Materials for Steam Boilers,) is  $= 1,030^{\circ}$ ; then will the total amount of heat received by the unit of water be expressed by l+(2!2-t); and by the water evaporated by 1 of coal,  $cw \times (l+(2!2-t))$ . To know the weight of water which would have been evaporated, had it been delivered to the boiler at  $212^{\circ}$ , the above quantity is divided by l, giving the formula  $cw + \frac{cw(212-t)}{l}$ .

terior return flues. This take passed through another of copper, permanently fixed in the wall of the furnace, and capable of being closed, when not required for drawing gas, by a suitable stopper of wood.

The iron tube had an enlargement consisting of about 4 inches of a musket barrel brazed to the smaller conducting tube. This enlargement was kept filled with asbestos moderately compacted together, but by no means precluding the passage of air. It served as a filter to strain from the gases collected all the solid impurities. With the exterior end of the small iron tube is connected, by a piece of gum elastic tube, the glass tube and bulb n, (fig. 1, plate 11,) filled with dried chloride of calcium, to arrest and absorb the moisture of the gas passing through it. But as this substance sometimes allows minute quantities of water to escape, a second tube, o, containing amianthus well moistened with concentrated sulphuric acid, was connected with the former, and served to render the gases perfectly dry.

These two tubes were placed near the furnace, that they might receive from the hot iron tube every portion of moisture without danger of being deposited in the leaden flexible tube which conveyed the gases to the next apparatus—that seen at p, which is a tube of Liebig; containing a strong solution of pure potash. Here the carbonic acid is absorbed, and the thry gas once more takes up a portion of moisture which the tube q, containing dry thioride of calcium, absorbs; allowing the gas in its dry state to arrive at the glass graduated jar r, inverted over mercury in a large well of the bath A, and suspended by a cord and counterweight, causing it to rise with any required degree of force necessary to draw the gas from the

chimney.

The jar r contained about 190 cubic inches, and was furnished with a steel cap and stopcock, by which it was securely closed. A stopcock, interposed between the leaden tube and that containing potash, served to cut off the access of gas, and to test the accuracy of the joints interposed between it and the collecting jar, by raising the latter two or three inches out of the mercary, and ascertaining whether any air gained admittance. Like precautions were afterwards taken to ascertain that the joints near the furnace, connecting the potash and sulpharic acid tubes with the iron pipe i, (fig. 1, plate 111,) and with the leaden tube, were all secure from leakage. The latter tube was 24 feet 5 inches long, one-fourth of an inch exterior, and one eighth of an inch interior diameter, and held 3.5 cubic inches. In the intervals of use, it was kept closed by the stopcock near the potash tube, and there was consequently little or no opportunity for the escape of the gas previously introduced.

The mercurial cistern had three "wells," or deep portions, which at the same time served for supports to the apparatus, and for receptacles of the jars containing the gases for analysis. It had also a horizontal trough, over which the re-agents could be passed up into the jars when required. When gas was to be drawn from the chimney, the large jar r was pressed into and completely filled with mercury, and its stopcock closed. The several glass tubes above referred to, containing the re-agents, were then carefully weighed, and their weights recorded. The potash tube and chloride tube, p and q, were then connected with the jar r, and with the stopcock e, (fig. 1, plate m;) after which, the soundness of the junctures was proved as above stated.

The other parts of the apparatus were then securely attached; and

finally the tightness of the whole series was tried before inserting the iron tube i (fig. 1, plate 111) into its place. This was done by putting a sheet of gum elastic over the end of it, on which the thumb of one assistant was placed, while another opened the stopcocks at the jar, and raised it some distance out of the mercury. When all these precautions had proved the satisfactory condition of the apparatus, the iron tube was inserted in its place, and the drawing of gas commenced by opening the cocks near the jar, or was suspended by closing them, at pleasure. It was made more or less rapid by the amount of the counterweight P, and by the extent of opening of the stopcocks.

The time of commencing and discontinuing the drawing was noted, together with the amount of gas drawn; and the temperature of the air near the mercurial bath was indicated by a thermometer kept suspended there for the purpose. The barometer was generally noted either during or soon after the time of drawing gas. As soon as the drawing ceased, the several glass tubes with their contents were detached and re-weighed. The gain of weight in the chloride tube and sulphuric acid tube near the furnace, marked the weight of water collected; and that of the potash and chloride tubes near the jar r, indicated the weight of carbonic acid; the last re-agent being intended to withdraw from the gas the moisture taken

up from the potash solution.

The height of the barometer being taken with every set of observations, served to determine the density of the gas drawn, of which the bulk was of course noted, after bringing the mercury within and without the jar to the same level. The amount of water due to the hygrometric state of the air passing to the furnace, was known by means of the two thermometers seen at e, e', (fig. 2, plate 11,) placed at the entrance of the air port beneath the ash pit, the bulb of one of which was kept dry, and that of the other moist, by means of a cloth with which it was wrapped, and which was wetted after each set of observations. The dew point derived from observations on these two instruments was deduced from the table of the Encyclopedia Britannica, of which the general correctness was tested by several direct trials made during the progress of the research.

The dew point determines the weight of moisture in a given bulk of air, and the excess weighed in the apparatus was attributed to the products

of combustion.

In the earlier experiments on this subject, the opening j (fig. 2, plate 11) was used for inserting the gas-collecting tube, and during the operation required that the lower damper should be opened. This invariably accelerated, to some extent, the combustion and the rate of evaporation; and though it could not essentially vary the proportion of materials collected, did not afford so satisfactory a proof of the relation between the fuel burned, and of air by which its combustion was effected, as when afterwards the copper pipe expressly appropriated to this object, and seen at i, fig. 1, plate 111, was inserted.

Having drawn into the jar r a sufficient quantity of gas, (usually from 80 to 100 cubic inches,) and ascertained its loss in transitu to the tubes above referred to, a portion was transferred to a smaller graduated jar s, with steel cap and stopcock, and was there tested for the amount of oxygen remaining. This was done by means of phosphorus passed up into the jar, and melted by bringing round the jar the curved jaws of a pair of

tongs heated to redness.

The proportion of gas condensed after becoming cool marked the proportion of oxygen in the residual gas. The weight of carbonic acid de-

termined its bulk at the temperature and pressure observed.\*

The accompanying table CXCIV exhibits those experiments in which all the principal ingredients of the products of combustion were determined, and may illustrate the objects in view while prosecuting these researches. The first fifteen columns of the table are devoted to the data obtained by experiments, and noted in the column of "remarks" in the several tables of daily observations.

Following these are twelve columns exhibiting the relations to each other, both by weight and by bulk, of the chief products of combustion,

calculated from the data furnished in the first division of the table.

The weight of water in 100 cubic inches of air, at the observed dew point, is first calculated from table CXCVI. This, applied with proper corrections to the quantity of gas which came to the apparatus, and deducted from the water collected in the experiment, furnished the second column of this part of the table; which, consequently, exhibits the weight of water derived from the combustion alone. From this, the bulk at standard temperature and pressure of the oxygen of that water, and the weight of its hydrogen, are readily calculated. The observed weight of carbonic acid gives the means of knowing the bulk of the oxygen, as well as the weight of the carbon which composed it. The condensation by phosphorus, with the observed temperature and pressure at the time the gas was drawn, affords the means of determining the bulk at a temperature of

In order to bring all the observations to a common standard, it is of course necessary to bring into the calculation the temperature and pressure at which each specimen of gas was drawn into

the jar.

If V be the observed column of dry gas taken into the jar, t the temperature at the time the drawing ceased, h the height of the barometer in inches at the same time, then would the bulk at  $60^{\circ}$ , under the same pressure, be  $\frac{521\,V}{493+(t-32)}$ . (This admits the expansion of air to be  $\frac{1}{493}$  d part from 32°, for every degree Fahrenheit, according to the recent determinations of Rudberg, Regnault, and Magnus.) When the observed pressure is not equivalent to 30 inches at the standard temperature, it is corrected to bring it to that standard by the formula  $h' = \frac{10018h}{9990+(t-32)}$ , where h' is the corrected height of mercury which would have been observed at  $60^{\circ}$  under the same pressure. Hence, since the volumes are inversely as the compressing forces,  $h': 30: \frac{521\,V}{493+(t-32)}$ : V', where V' is the true volume of dry gas at  $60^{\circ}$  and 30 inches barometer.

Since the bulk of carbonic acid is the same as that of the oxygen which enters into its composition, its relation to the total volume of dry gases, before arriving at the potash tube, is found by the ratio  $\frac{q}{V+q}$ , which may represent the per centage of oxygen taken from the air, to constitute the carbonic acid.

As the treatment with phosphorus gave the ratio which the oxygen bore to the total amount of gas collected in the jar, this ratio may be called r; its bulk in cubic inches is known by taking the product rV, and its relation to the sum of dry gases will be  $\frac{rV}{V'+q}$ . In these computations no account is taken of the phosphoric compounds.

As water contains eight ninths of its weight in oxygen, the bulk of the latter gas, belonging to any observed weight of water collected, is found by taking that fraction of the observed weight and dividing it by .341872, which is the weight in grains of one cubic inch of oxygen at 60°

Fahrenheit and 30 inches barometer.

<sup>\*</sup> Having the weight a in grains troy, of any quantity of carbonic seid, its bulk in cubic inches at a temperature of  $60^{\circ}$  and a pressure of 30 inches in the barometer, will be found by the formula  $q = \frac{100a}{47.862}$  where q is the bulk required in cubic inches.

of the jar, as well as of the oxygen absorbed; and these, with the previously determined amount of carbonic acid, show the original volume of dry gases which arrived at the potash tube p, (fig. 1, plate 11.) This volume is seen under the head of "total of dry gases collected." Following this, are three columns appropriated to exhibiting the ratio to the total of dry gases, first of the carbonic acid and of the residual oxygen separately, and then of their sum; in order to determine how nearly this latter relation approaches that of oxygen in pure atmospheric air. It will be observed that many of these numbers closely approximate to that relation as established by chemists, viz: 20° per cent. It will also be found that the average proportion of oxygen left in the air drawn into the jar was, by 71 trials on about 30 varieties of coal, 12.03 per cent. of that air, or 52.5 per cent. as much as would, with the same quantities of nitrogen, have constituted atmospheric air.

This result agrees pretty nearly with some which were obtained at the very time these experiments were in progress, by Mr. Robert Hunt,\* from trials on several of the large Cornish engine furnaces. He found the condensation by potash to amount to one-ninth of the whole volume of gas drawn from the chimney; and of the remaining gas, one-tenth was condensed by phosphorus. My experiments also accord with what is stated by M. Peclet† relative to those made at Vesserling in 1832, from which it appeared that the quantity of oxygen found in the smoke of the chimney of a steam-boiler furnace, varied from 10.5 to 11.5 per cent. while using coal, and from 4.55 to 7 per cent. when burning wood. This author assumes in his calculations that one-half of the air which goes to

the grate of a furnace using coal escapes unburnt.

The remaining thirteen columns of the table are consigned to deductions relative to the heating power of fuel. From a knowledge of the proportion of earthy matter in each coal, and of the carbon and hydrogen derived from its combustion, the quantity, in grains, of raw coal burned by the agency of the gases collected, is ascertained. From this, the bulk in cubic feet at standard temperature and pressure, and the weight in pounds of atmospheric air, sufficient to burn one pound of the raw coal, become known; and also, from the relation of the several gases collected, and their specific heats, the weight of air equivalent in specific heat to the dry gases for a pound of coal, is calculated, and is readily converted into weight of water, equivalent in heat-absorbing power to that weight of air. The water of combustion for one pound of fuel is calculated from the previously ascertained excess of that collected, above the hygrometric moisture; and the latter, for one pound of coal, is separately obtained from the balk of air found necessary to burn a pound of coal, and from its observed dew point. The last five columns of figures in this division of the table are appropriated to recording the evaporative power of the several quantities of heat which were employed—1st, in raising the temperature of the air which supplied the combustion, from that at which it entered the air port, to that at which it reached the chimney; 2d, in vaporizing the water derived from the coal, and afterwards heating it to the tempera-

<sup>\*</sup> See Practical Mechanics and Engineers' Magazine for December, 1843, page 93, article IV. Those experiments were made in June, August, and September, preceding their publication.

† Traité de la Chaleur, considérée dans ses applications : tom. i, p. 8.

ture at which it passed into the chimney; 3d, in raising the hygrometric moisture from its initial temperature to that possessed by the gases going into the chimney; 4th, and finally, that employed on the steam generated from the boiler at 212° by one pound of raw coal. The last column of numbers in the table is obtained by adding together the four immediately preceding.

## 12. Apparatus employed in the ultimate analysis of coals.

The section of an apparatus used for drying the specimens of coal analyzed, is seen in plate 1, fig. 1. A is a copper boiler about 8 inches high, by 6 in diameter at the base, furnished with an interior cylinder B, shout 54 inches deep, and 3 inches in diameter, closed at bottom, and open at top to receive the small movable system of shelves c, on which are supported capsules, b, b, b, b, containing the pulverized coal to be dried. A lid, D, closes the mouth of the interior cylinder. A screw, N, closes steam tight the opening through which the boiler is filled. A tubulure, T, connected with a glass tube, t, bent at right angles, conveys the steam down to a distance of 8 feet, to a jar, E, containing mercury, into which the tube descends to a depth of about 5 inches. A basin to receive the condensed water which may flow from the surface of the mercury, serves as a support to this jar. A lamp, L, is placed beneath the boiler as it rests on the tripod S. Fig. 2 exhibits, on an enlarged scale, the frame of shelves c, withdrawn from the boiler. The arrangement above described enabled me to apply to the specimens a temperature of 216° for any desirable length of time; by leaving the lid D resting rather loosely over the mouth of the cylinder B, a certain amount of circulation of air was allowed, favoring the rapidity of the desiccation.

On the same plate, at fig. 9, is seen an arrangement for securing accuracy of junctures in connecting the successive parts of the apparatus employed in the analyses. A is the sheet-iron furnace; C the combustion tube, covered with thin sheet copper; and that with sheet iron firmly secured with thin iron wire. These precautions were found necessary, owing to the easy fusibility of American green glass tubes, which, without this safeguard, would generally give way under a heat much below what is desirable in analyzing coals.

P is a sheet iron screen to shield the several tubes containing the absorbing apparatus from the heat of the furnace; t is the tube for chloride of calcium with its bulb, and having its beak entering a cork, which closes the mouth of the combustion tube C. To insure accuracy in this joint is not always of easy accomplishment. In using an exhausting syringe, or a common air pump, for this purpose, the number of joints in those instruments renders their indications rather equivocal. But the mercurial pump E answers this end perfectly. It is a glass jar about 1 foot high, and 2 inches in diameter, rather more than half filled with mercury. Into this liquid descends the inverted jar D, open at bottom, and drawn out above into a tube, the upper end of which is connected by the elastic joint e, with the tube B, about 3 feet in length, which is in turn united by the elastic tube f, with the chloride tube t. When the junctures are first made, the The mercury within jar D is depressed so as to rest on the bottom of E. and without D is then at the same level. By raising D, the mercury within it rises to the height say of h, while that exterior to it falls proportionally. The distance m, h, then represents the column of mercury (which may be from 3 to 6 inches) that exerts its force to draw air into the combustion and chloride tube. A line encircling the jar at h serves as a marker to determine whether, when raised to that level, the mercury in D continues constant at the same height. A very few minutes determines this conclusively.

In detaching the pump, the joint e is not disturbed, nor the attachment of f to the tube B; so that a single tying only is required to connect it

with the next piece of apparatus required to be tested.

Fig. 4 represents the apparatus at the conclusion of an experiment. The end of the combustion tube C, however, instead of projecting out of the furnace two or three inches, came only about one inch, or less, in front of the screen P. The limiting screen e, which during the progress of the combustion had been pushed successively from P to A in the furnace, is removed.

The upturned point of the combustion tube, as seen at C, fig. 3, has been broken off, to admit the passage of air through the tube; the calcium tube D, closed at bottom with a perforated cork, has been placed over the opening. A cork, fitting loosely at the upper end, allows air to pass freely down the tube, when, by the action of the pump H, air is drawn through the combustion tube, to sweep out the last portion of the products of combustion; t is a chloride of calcium tube; s a tube and bulb, containing amianthus moistened with concentrated sulphuric acid. L and L' are Liebig's tubes, containing concentrated solutions of potash; m is a calcium tube, to arrest the moisture taken up from the potash liquids; n is a tube for sulphuric acid and amianthus.

It will be understood that, during the progress of combustion, the leaden tube r was disconnected from the rest of the apparatus, and any gas not condensed by the re-agents made its escape at the beak of the tube n.

The glass tube I, descending into a jar containing mercury, served as a gauge to mark the force employed in drawing the gases through the apparatus. It may be proper to remark, that, in experiments in which chlorate of potash was placed at the bottom of the combustion tube, to drive out the products of combustion by means of the oxygen which it furnished when decomposed, the use of the air pump was unnecessary.

It is hardly necessary to state that each of the pieces of apparatus, t, s, L, L', m, and n, was separately weighed in a delicate balance, both before and after the performance of every experiment, in order to obtain the exact gain of weight from absorbing the condensable products of combustion.

13. On the hygrometric character of the different materials employed to produce the combustion of organic compounds, employed in this research.

The chromate of lead has been recommended for this purpose, on account of its being absolutely destitute of all tendency to absorb moisture.

The oxide of copper precipitated from the nitrate, is well known to be a very active absorbent of water, rendering necessary all those minute and troublesome expedients to avoid excess of moisture, which are laid down in treatises on organic analysis.

The chlorate of potash is regarded as a dry salt destitute of hygromet-

ric properties.

Having determined to make trial of finely pulverized oxide of copper,

procured from the sheet-copper manufactory, I first calcined 525 grains for more than an hour in an open muffle, to convert dinoxide into protoxide. This gave an increase of weight amounting to 32.82 grains, showing that 292.018 grains, or 55.62 per cent. of the whole, had received the requisite quantity of oxygen to effect that conversion.

After pulverizing completely the calcined oxide, a portion weighing 362 grains was placed in a porcelain crucible, with the same weight in another crucible of freshly ignited oxide, precipitated from the nitrate of copper. These were then placed side by side on a porcelain tile resting on a moistened cloth, and the whole covered with a half-gallon glass evaporating basin inverted over them. The moisture soon filled the interior of the basin, where the temperature ranged for 15½ hours from 45 to 60 degrees. The precipitated oxide had at the end of that time gained .61 grain, while the scale oxide had imbibed only .11 grain; or the former had absorbed 5.54 times as much as the latter. To compare chromate of lead with the oxide of copper, I put 250 grains of scale oxide, and the same weight of chromate of lead, into two separate crucibles; placed them in a muffle, and heated them nearly to redness. Each lost .08 grain. They were then placed under a basin over a damp cloth. Here they remained 24 hours surrounded with vapor which condensed copiously on the glass above them. By this exposure the crucible containing oxide of copper gained .18 grain, and that containing chromate of lead .48 grain, or nearly three times as much.

It appears that the moisture weighed on the cup containing scale oxide of copper, had been mostly attached to the cup itself; for, after standing 21 hours in an atmosphere at 40°, it had returned to its original weight, while the chromate of lead still retained an excess of .14 grain; fully proving that the latter material was more hygrometric than the former.

In a third trial, I put under a basin three cups, one containing scale oxide, one precipitated oxide of copper, and the third fused chromate of lead. Having all been exposed 48 hours in damp air under a basin, the scale oxide cup had received an increase of .09, the chromate of .16, and the precipitated oxide .22 grain.

The contents were removed from the several cups, and the latter thoroughly dried. When returned to them, it appeared that the scale oxide and chromate lost all their excess of weight by one hour's exposure on a table at a temperature of 60°, while the precipitated oxide still retained .12 grain of that excess.

It appears that these several powders had contained, when put under the basin, some portion of moisture; for, on exposing the three at a temperature a little below redness, for half an hour, the scale oxide lost .10 grain, the chromate .14, and the precipitated oxide .19 of a grain.

These cups were now loosely covered with their respective lids, to keep out dust, but not to prevent the ingress of air and its moisture; and in that condition left, for one year, exposed to the variable condition of air. It was then found that the scale oxide cup had gained .05 grain, the chromate cup .11, and the precipitated oxide .17; the second being more than twice, and the third more than three times as much as the first.

Of chromate of lead in its raw state, I put 154.66 grains into a small

sand crucible, and brought it to incipient fusion. It lost 2.06 grains.

Of fused and subsequently pulverized chromate, I weighed into the same crucible 439.02 grains, heated it to incipient redness, when it was

found to have lost .22 grain. The crucible had been heated by itself just before this trial, and lost .1 grain.

. I heated chlerate of potash to 390°, or to incipient fusion, by which it

iost .808 per cent.

From all the foregoing experiments, I am led to the conclusion that scale oxide of copper is more free from tendency to absorb moisture than any of the other materials assayed, and that it absorbs with such extreme

slowness as to be practically anhygrometric.

The above experiments, and the analysis which I made with the scale oxide of copper, having led me to give the preference to this oxide above that procured by precipitation, (contrary to the recommendation of every treatise which I have consulted on the subject,) I have been pleased to find that the conclusion I had formed respecting the utility of this material is in accordance with the practice of the great master of organic chemistry himself. A gentleman\* who has spent some time in the laboratory of M. Liebig, has informed me that the scale oxide of copper produced in the sheet-copper manufactory, is the substance now employed at Giessen to produce the combustion of organic bodies. The reduction to the state of peroxide is there effected by moistening the scales with nitric acid and heating in an earthen crucible; some nitrate is formed, but is decomposed by subsequent iguition.

J. Lawrence Smith, M. D., of Charleston, S. C.

#### CLASS I.

#### ANTHRACITES-NATURAL COKE-ARTIFICIAL COKE-MIXTURES.

#### SAMPLES.

## General characters of the class.

The anthracites have specific gravities varying from 1.39 to 1.51; retain their form when exposed to a heat of ignition, and undergo no proper intumescence while parting with the small portion of volatile matter which they contain; or, if changed at all, are only disintegrated into angular fragments. Their flams is generally short, of a blue color, and consequently of little illuminating power. They are ignited with difficulty; give an intense concentrated heat; but generally become extinct while yet a considerable quantity remains unburnt on the grate.

#### No. 1.

Anthracite coal sent by the Beaver Meadow Railroad and Coal Company from the mine called "Slope No. 3" of said company.

This and the succeeding sample were accompanied by the following certificate:

"Office of Beaver Meadow Railroad and Coal Co.,
"Philadelphia, June 17, 1842.

"I certify that the (10 casks) coal were mined since last winter. Five casks, marked No. 3, are coals from our mine No. 3; and 5 casks, marked No. 5, are coals from our mine No. 5. There are but about two tons of each kind. Bristol, on the Delaware river, is the most convenient port for the delivery of it for shipment. We can have ready there large quantities of either kind, by giving due notice to this office.

"ROBERT PEARSALL,
"President."

The state of this coal when received, (June 30, 1842,) as well as when burned, (June 30, 1843,) was that of lumps or masses of considerable magnitude—too large, indeed, to be either conveniently or profitably burned; and it consequently required to be broken up into fragments of

such size as to be capable of a speedy and sustained ignition.

The aspect of the coal is generally characterized by an irregular fracture; a rather dull black color; a surface marked by minute striæ; and presenting, in many specimens, portions dotted with minute brilliant specks, which a close inspection shows to be composed of circles, or concentric rings, of which all the planes are parallel to each other. These marks of a definite internal structure can of course be seen in one position only on each of two opposite sides. The fracture is sometimes conchoidal and splintery. The surfaces of deposition are in general but faintly marked, until a partial combustion has developed them; they then become sufficiently apparent.

The specific gravity of two specimens was found to be 1.6104 and 1.6102; from which the calculated weight of a cubic foot of the solid

coal, as it exists in the mine, is 100.645 pounds.

The mean result of forty experiments in measuring and weighing the coal as it came to hand, gave the weight of a cubic foot in its merchantable condition 54.925 pounds, or .5487 of the calculated weight just stated. Hence the space required to stow one gross ton of this coal is 40.78 cubic feet.

The two specimens of which the specific gravity is given above, were submitted to analysis: the first contained of moisture 1.005, and the second 1.296 per cent. These determinations were made by means of the

apparatus seen at fig. 1, plate 1, already described.

During the progress of experiments on evaporative power, 28 pounds of this coal were placed for twenty-four hours in the copper steam-drying bath K, (fig. 1, plate 111,) where it was subjected to a temperature of rather more than 212°; and in that time it lost 7 ounces in weight, or 1.562 per cent. 100 grains of the second specimen above referred to, reduced to an impalpable powder, and treated with two drachms of concentrated pure nitric acid, and digested for twenty-four hours at a moderate sand heat,

filtered and treated with chloride of baryum, yielded of ignited sulphate

of baryta .08 of a grain—equivalent to 0.011 per cent. of sulphur.

Of the same specimen, 20 grains treated with pure English litharge reduced 583.36 grains of metallic lead, or 29.168 times its own weight. A second trial gave 28.3 times its weight. (It seems probable that, in the latter case, some portions of the anthracite must have escaped complete reduction.)

Four trials on each of the two specimens, to determine the proportion of incombustible ingredients, resulted in giving for the first 10.91, 11.09, 11.14, and 11.05 per cent., or an average of 11.05; the weights employed being from 30 to 55 grains at each trial. For the second specimen, the numbers were 8.77, 8.79, 8 55, and 8.67, or an average of 8.69. The incineration was continued from 4 to 5 hours.

The ashes from analysis are of a grayish white color, tolerably dense, and tend to cohere slightly together into masses. By a reference to the following tables, it will be seen that the proportion of waste, including clinker and ashes, in the several trials of this anthracite, varied from 9.039 to 16.452 per cent. of the fuel burned. Taking the entire amount of coal actually consumed, 3,944.5 pounds, and the total weight of waste from the four trials, viz: 469.88 pounds, we find the per centage of the latter 11.912. The ratio of the clinker to the total waste was but 9.1 per cent., and the color and appearance of the substance such as to indicate but little tendency to fusion and vitrification in the earthy ingredients of this anthracite. No tendency to adhere to the grate bars was observed.

The ashes from the furnace are of a gray color, pretty abundantly mixed with particles of unburned anthracite. In trials of this, as well as other samples, it will be observed that the higher proportion of clinker was found after those experiments in which the combustion and evaporation had been most accelerated. Thus, in the 1st and 3d trials, in which the damper was drawn 10 inches, the ratios of clinker to ashes are 14.796 and 8.976; while in the 2d and 4th trials, with the damper set at 5 inches, the

The weight of a cubic foot of the ashes of this coal was found to be 52.89 pounds, and of an equal bulk of its clinker 34.07 pounds. Of the dust from the flues, mixed with a little soot of the wood used in raising temperature at the commencement of each experiment, the weight was 21.39 pounds per cubic foot. The ashes, when exposed again to incineration for several hours on a platinum capsule, lost 44.33 per cent. of their weight, leaving a slightly reddish gray powder. The ashes being 90.9 of the total waste, the reduction from burning out completely the combustible residuum is 40.295 per cent. of 11.912, or 4.8; leaving 7.112 as the true per centage of incombustible matter of this coal, exclusive of the dust of the flues, and showing that both the specimens above analyzed gave more than the average amount of earthy matter. Of soot and dust, only 3 lbs. and 14 ounces were collected on sweeping the flues after four days' burning; and of this small amount, 32.28 per cent. was combustible matter; leaving but 2 lbs. of ashes attributable to the anthracite alone. The importance of this freedom from coating in the flues, is seen in the table of deductions, where, instead of finding a falling off in the "water from 212° to 1 of combustible matter of the fuel," we have the highest result at the fourth trial.

The volatile matter, other than moisture, was found to be only 2.335 and 2.234 per cent. in the two specimens analyzed; so that of the first,

ratios are 6.5014 and 6.1315.

the total volatile matter was 3.34, and in the second 3.52 per cent. Hence we have—

Volatile matter	•	-	-	•	-	1st specimen. 3.34	2d specimen. 3.52
Earthy matter	-	•	-	•	•	11.05	8,72
Fixed carbon	•	, <b>-</b>	-	-	-	85.61	<b>37.76</b>
						100	100

Admitting that the volatile matter above given is a fair average of that generally contained in this anthracite, and knowing from the trials of ashes already stated the true amount of earthy matter on a large scale, we have the following result:

Volatile matter (mean of two trials) = 3.430Earthy matter (from 3,944.5 lbs.) = 7.112Fixed carbon - - 89.458100

It is proper to add, that four trials of volatile matter in specimens from this sample of coal by Dr. King, gave a mean of 4.462 per cent.; which, with the two above given, yielded a mean of 3.946, reducing the fixed carbon to \$8.942.

The difficulty of ignition will be, in part, understood from the fact that the boiler was not in steady action in the first trial until 5 hours and 3 minutes after the charging with coal commenced. In the second trial, this time was increased to 5 hours and 43 minutes, notwithstanding that the first charge had been laid upon the grate before the fire of pine wood was commenced. In the third trial, the time was reduced to 2 hours and 45 minutes, having the same advantage of a charge of anthracite laid upon the grate before charging with wood. At the fourth trial, the time was farther reduced to 1 hour and 55 minutes. It appears, therefore, that the average length of time required to bring the furnace into full activity, after the kindling wood was withdrawn, was 3 hours and 52 minutes = 3.866 hours.

Another evidence of the difficulty of ignition is found in the table of deductions opposite to the title "pounds of coal withdrawn and separated after trial," which, on an average of the four trials, was 112# lbs.

When broken to egg size, this coal gave, by three trials which were identical in their results, 57.25 lbs. per cubic foot.

Though it is well known that, in the anthracite coal districts of Pennsylvania, the materials there obtained from the mines are the only ones used by smiths for any of the purposes of their trade; yet as, among the namerous artisans of this class at the Washington navy yard, I could find none acquainted with its use in common forge fires, I was compelled to forego the experimenting which Pshould otherwise have felt it a duty to prosecute on this part of the subject. The adaptation of the particular kind of anthracite now under consideration to the purpose of working iron, either in close or hollow fires, cannot be doubted; provided the requisite experience and skill, and the proper arrangement for effecting the production and application of its heat, be brought into requisition.

The combustion of a portion of this anthracite in a well-constructed office grate, showed it to be rather more difficult of ignition than the (so called) red-ash coals. It is a fair type of the gray or white-ash anthracites of the eastern end of the southern and middle coal fields of Pennsylvania,

both in regard to exterior characters and general behaviour while undergo-

ing combustion.

In the table of deductions, following those of the experiments, will be found a synopsis of the general results obtained in regard to its evaporative power. In that table are 47 lines—of which Nos. 2, 11, 12, and 25, are approximations, depending on the estimated weight of coal on the grate at the beginning and ending of "steady action" for the day; and Nos. 20, 21, 22, 23, and 25, are dependent on the observations respecting the height of water in the boiler at the same periods.

The following remarks apply generally to the tables of experiments:

The period of steady pressure, and that of steady activity of evaporation, are generally different—the former being usually longest. dotted lines embracing the first of these periods, will be seen to commence on the left of the table, and include in their range the column of "dew point, by calculation," and that of the "gain of temperature of air before reaching the grate." The lines denoting steady pressure commence at the column headed "height of water in syphon," and extend to the right of the table, with the exception of the two columns above mentioned. The numbers in the column of "differences of temperature between steam and escaping gases" will, in some instances, be found marked with the sign — before them, to signify that the escaping gases were then at a lower temperature than the steam; whereas when the sign + is used, or when the number is without any sign, the gases are indicated to have been hotter than the steam. In the column of "remarks" will be found noted the time when the water cistern was replenished. This serves to explain any irregularity which may happen to occur about the same time in the rate of supplying water to the boiler, which, as already noted, was necessarily suspended during the time of refilling. The same column contains such notes on the state of the atmosphere as were considered to have a bearing, more or less direct, on the other observations relative to -combustion.

## Explanation of the table of deductions.

In explanation of the preceding, and all the similar tables of deductions which occur in this report, it may be stated, that the 1st line, " Total duration of experiment, in hours," refers to the time when the fire was lighted to commence the experiment, to that at which the level of water in the boiler had been adjusted, and the last set of observations recorded. It will often be found that the moment of ending one experiment is that of commencing the next; and that, in fact, the same set of observations served for both. The 2d line, "Duration of steady action, in hours," is a period selected for the comparison of various related quantities requiring consideration in treating of combustion and evaporation. determination of this period was generally fixed by an examination of the 19th column of each table, in which the water evaporated per square foot of absorbing surface is given. This period is assumed from the time that some one of the charges of coal had been all placed upon the grate. The 3d line is devoted to recording the "area of the grate, in square feet," during each trial. In general, it remained the same for all the trials of the same sample, but occasionally varied, even while trying the same coal. The 4th line denotes the area of the boiler and its flues exposed to the fire, or to the current of flame and hot gas passing from the furnace to the chimney. "The area of boiler exposed to direct radiation," is intended to denote only that part of the lower arch of the boiler which was directly above the fuel on the grate. The 6th, 7th, 8th, and 9th lines explain themselves. The mean weight in pounds of one cubic foot of coal, is in all cases found by dividing the total weight of all the charges recorded, by double their number.

At the bottom of each table of experiments will be found a statement of the coal supplied during the period of steady action. That weight divided by the length of that period in hours, as contained in the 2d line of the table of deductions, gives the 11th line, viz: pounds of coal supplied per hour during steady action; and the latter again divided by the number in the 3d line, affords that in the 12th line, or the pounds of coal per square foot of grate surface per hour. The whole amount of ashes and clinker contained in the remarks at the foot of each table of experiments, divided by the number in the 8th line, gives the per centage of waste entered in the 13th line of deductions. The weight of clinker alone, divided by the weight of coal actually consumed, gives the number in the 14th line. The number in the 14th divided by that in the 13th line, gives the ratio of clinker to the total waste contained in the 15th. The numbers of the 16th line are derived from the last number in the 13th column—that which records the weight of water supplied to the boiler, in each of the experimental tables. The 17th line is derived from the 6th column of the experimental tables, "temperature of water in tank," by dividing the sum of the numbers between the horizontal dotted lines crossing that column, by the number of observations recorded within the period of steady pressure, which those dotted lines are intended to indicate. The pounds of water supplied at the end of experiment to restore level, in the 18th line, are known from the difference between the number in the 16th line, and that which in the table of experiments belongs to the last set of observations on the preceding day. Thus, in table I, we have the last number in the

column of "weights of water supplied to boiler," 8,801 pounds recorded on the morning of the 29th of June, and the last number entered on the preceding evening 7,654. The difference of these, 647, will be found as the first number in the 18th line of the table of deductions. The 19th line contains the calculated reduction which ought to be made on account of the last portion of water having been evaporated from the temperature of 230°, instead of the mean temperature of water in tank, as found in the 17th line. This reduction is found by multiplying the weight of water supplied to restore the level, by the difference just mentioned, and dividing by the sum of the sensible and latent heat of steam produced from water of the temperature observed in the tank. Thus,  $647 \times (230-84) \div 1154 = 81 + ;$  and this latter is the number under the first trial in the 19th line of deductions.

The water supplied to the boiler during steady action, found in the column of "remarks" of the tables of experiment, divided by the numbers in the 2d line, gives that in the 20th; and the latter, divided by 62.5, (the weight, in pounds, of one cubic foot of water,) gives the number in the 21st line—"cubic feet of water per hour during steady action." The number of the 20th line, divided by that of the 4th, (area of heated surface,) gives the number in the 22d line. The 23d line is derived from the 19th column of the experimental table, by taking the mean of the numbers embraced between the horizontal dotted lines, which there include the period of steady activity of the boiler, not merely that of steady pressure, as above designated. It will be observed that the numbers in the 22d and those in the 23d line do not always coincide. This may be accounted for by the fact, that the time elapsed between two consecutive observations is not always the same during the period of steady action. The difference between the numbers in lines 16 and 19, divided by that in line 8, gives the number in line 24, viz: water evaporated by one of coal from initial temperature, which is the "final result" of the day's operations, subject only to a slight correction hereafter to be noticed, (line 40.) The number in the 25th line is derived from a division of the 20th by the 11th. It is, of course, like all the other numbers, dependent on the observation of the mass of coal at any moment on the grate—only an approximation, more or less near, to the preceding line. It is useful in determining what reliance is to be placed on the other deductions depending on the same observation. In comparing the averages in 42 tables of deductions, it will be found that in 23 cases, lines 24, or the "final results," are higher than lines 25, or results during "steady action;" and that 19 cases of the reverse occur. The total of the averages on lines numbered 24 is On those numbered 25 is 322.90

The difference of which

is 1.5 per cent. of the upper number. The total weight of coal consumed, divided by the total weight of water evaporated, reduced to cubic feet. gives the number in the 26th line. The mean of the numbers included in the 2d column of the experiment table, between the dotted lines limiting the period of steady pressure, furnishes the number in line 27th; column 3d furnishes in a similar manner the number in line 28th; column 4th gives line 29th; column 5th, line 30th; column 7th, line 31st; column 8th, line 32d; column 9th, line 33d column 11th, line 34th; col-

umn 10th, line 35th; column 12th, line 36th. In this last case, it is the period of steady action which is limited by the horizontal dotted lines; not that of steady pressure, as in several of the preceding. Line 37th is derived by taking the mean of the numbers' between the dotted lines in column 16th; line 38th, in a similar manner from column 17th; and line 39th, from column 18th, as limited by the dotted line of steady action. Line 40 is obtained by multiplying the number in line 24 by the coefficient of expansion of water (as given in a preceding part of this report) for the mean temperature, as contained in line 17th. The number in line 41 is found by multiplying that in line 40 by the sum of the sensible and latent heat imparted to the water, and dividing by the latent heat of steam at 212°. The number in the 41st line, multiplied by that in the 10th, gives the weight of water evaporated from 212° by one cubic foot of coal, as contained in the 42d line; and, again, the number in the 41st, divided by the per centage of combustible matter of the coal, (obtained by deducting the number in line 13th from 100,) gives the number in line 43. The mode of obtaining the numbers in lines 44 and 45 has already been explained. The entries in lines 46 and 47 are taken from the headings of the tables of experiments. The averages of so many only of the foregoing deductions have been taken as are necessary for forming the synoptical table at the end of each class of coals.

## No. 2.

## Anthracite from Beaver Meadow Railroad and Coal Company's mine No. 5.

This coal, referred to in the certificate already copied, was received at the same time, and in a similar condition as regards size of pieces, with

that just described.

In external characters, it differs to some extent from that sample. The color is jet black; lustre brilliant; fracture variable, uneven, splintery, and often flat-conchoidal. The surfaces of deposition are seldom followed by the fracture of the coal. A slight iridescence is occasionally seen, indicating the presence of a film of sulphuret of iron. The specific gravities of two specimens were found to be, respectively, 1.5529, and 1.5491; and the calculated weight of a cubic foot in the mine is 96.93 pounds, whereas the actual weight of the coal as received was 56.324 pounds per cubic foot, as determined by forty trials of weight in the charge box, requiring 39.77 feet of space to stow one gross ton. From this statement, it appears that the weight in the merchantable condition is to the calculated weight in the mine as 0.5797 to 1. Three boxes reduced to egg size gave respectively 111, 1143, and 112 pounds per box, or, on an average, 56.29 pounds per cubic foot.

The proportion of moisture obtained in the analysis of the two specimens above referred to was 1.823 and 1.6, which appears to have been above the average; since 28 pounds, exposed in the drying apparatus connected with the boiler, gave in three days a loss of only four ounces, or 0.892 per cent. The trial of 100 grains of the specimen having a spe-

cific gravity of 1.5491, yielded of sulphur .062 of a grain.

The total volatile matter, by a mean of two trials, was found to be for the same specimens 3.68 per cent. Four trials by Dr. King on two other specimens of this coal gave a mean of 5.312; so that the mean of four specimens is 4.496. The quantity of earthy matter in this anthracite, as determined by four trials on each specimen, was 2.22 per cent. for the first, and 2.7 for the second.

The character of the ashes obtained in this analysis is that of a light fawn-colored powder, of moderate density, exhibiting no tendency to agglutinate at the temperature employed to produce the incineration, which was that of a muffle kept for some hours at a very bright red heat. In the trials of evaporative power, as exhibited in tables VI, VII, VIII, and IX, which follow, it will be seen that the amount of waste, including both clinker and ashes, with such portions of fine anthracite as escaped separation by the sieve, varied from 5.722 to 7.696 per cent. in the respective trials; and that it was on an average 6.745 per cent. The number of pounds of coal actually consumed was 4,250.5; and the total waste, after deducting the ashes of wood used in raising temperature, was 263.043 pounds, or 6.659 per cent. of the whole. The total clinker was 26.5 pounds = 0.6224 per cent. of the coal.

The actual mean proportion of earthy ingredients and metallic oxides in

this sample was found to be 5.149 per cent.

Admitting the six trials for volatile matter to furnish a fair average of that material, viz: 4.496 per cent., and this determination on the large scale to give the true amount of earthy ingredients, we shall have for the fixed carbon 90.355 per cent.; whereas the analysis of the two hand specimens gave—

Volatile matter - - - 3.68

Earthy matter - - - 2.46

Fixed carbon - - 93.86

The ashes are of a dark gray color, and weigh 51.4 pounds per cubic foot.

The clinker is mostly in small fragments—partly dark iron gray, partly yellowish white. The lighter colored portions are porous and friable, darker portions fused; none very compact. Weight per cubic foot, by ex-

periment, 35 pounds.

The material swept from the flues after four days' burning of this anthracite was 7 pounds, weighing at the rate of 26.97 pounds per cubic foot; showing a greater density than that of any other sample of soot and dust obtained during this research. As the carbonaceous matter was wholly derived from the wood, it might be expected that the remaining material in the flues should be found approximating the weight of the earthy matters of the anthracite. Such will, in general, be found to be the case; and the difference in this respect between coals of this character, and those highly bituminous coals which send forth a copious volume of black smoke, will be sufficiently marked. The times required for bringing the boiler into steady action, after the charging with this coal had been commenced, were as follows:

First trial -	•	•	-	/ -	2.00 hours.
Second trial -	-	-	•	•	3.50 "
Third trial -	•	•	-	•	1.416 "
Fourth trial -	-	-	-	•	2.75 "
•					-
. Mean	-	•	•	•	2.416 "

This indicates a greater facility of ignition than was found in the preceding sample; and the relation between the two is expressed by the numbers 2.416 and 3.866.

The quantities of anthracite withdrawn and separated after the several trials, were 89, 42.75, 66, and 47.5 pounds, or an average of 61.31 pounds;

while for the preceding sample the average is 112# pounds.

The general principle, that the slowness in bringing the boiler to steady action, and the amount of unburned anthracite left on the grate, are alike indicative of the difficulty of commencing and sustaining the ignition of the anthracites, is rendered at least probable by the approximate relation between the above numbers. For 3.866: 2.416::112.375:70.25. The last number is the calculated amount of unburnt anthracite in the sample now under consideration; whereas experiment gives 61.31.

In submitting specimens of both this and the preceding sample to complete ignition, either in a platinum crucible or an iron retort, the form of the fragments remained unaltered. A combastible gas, which burned with a light blue flame, accompanied in some cases with minute scintillations of a brighter light.

#### Anthracite of the "Forest Improvement" Company.

This sample of coal came to hand accompanied by the following certificate from the superintendent of the company, by whom it was sent:

"I certify that the anthracite coal forwarded to the navy yard, Washington, in the casks marked 'Forest Improvement,' was mined in August last, on the land of the Forest Improvement Company, in the township of Branch, and county of Schuylkill, and State of Pennsylvania, from the vein known as the 'Forest vein.'

"I further certify that the said coal has been promiscuously taken at New York from a cargo delivered to the Jackson ferry, in New York, for consumption, and is a fair sample of all the coal delivered from the Forest vein; that the said Forest vein is uniformly free of slate or other impurities; and that any desired quantity can be delivered for a series of years—Philadelphia being the port of shipment.

"Schuylkill Haven, (Pa.,) September 14, 1842.

"CHARLES DE FOREST,

"Superintendent Forest Improvement Company."

The exterior characters of this anthracite are somewhat different from those of either of the preceding. The main cleats, or partings, are marked by thin lamellæ of white earthy matter, apparently composed of sulphate of lime. These partings, however, are only observable in two positions of the specimens, and but little affect the general color of the coal, which is deep black, with occasional approaches to blue-black, in parts slightly tinged with oxide or sulphuret of iron.

The fracture is uneven, seldom conchoidal, and only occasionally taking place at the surfaces of deposition—revealing, however, when this does occur, moderately abundant deposites of mineralized charcoal in the seams.

The specific gravity of two specimens was found to be 1.4799 and 1.4741—the mean of which would give the calculated weight of a cubic foot of coal in the mine 92.31 pounds; while thirty-seven trials by measuring and weighing in the charge box gave its weight, in the condition of lumps as received, 53.658 pounds per cubic foot—requiring, of course, 41.74 cubic feet of space for the stowage of one gross ton.

The ratio of the computed to the actual weight of a cubic foot is 1 to

0.5812.

A bex of this anthracite broken to the "egg" size was found to weigh 106 pounds, or 53 pounds to the cubic foot; proving that no advantage, in point of stowage, would be derived from reducing it to this state.

Trials on portions of the two specimens above referred to, reduced to powder and dried in the apparatus fig. 1, plate 1, gave for moisture 1.162 and 1.213 per cent., respectively; and 28 pounds dried for three days in the apparatus connected with the boiler, showed a loss of 8 ownces, or 1.785 per cent.

By exposure to full ignition, the two specimens lost, in addition to the moisture, 3.158 and 2.437 per cent., respectively, giving the total volatile matter 4.32 and 3.65. In two specimens tried by Dr. King, the volatile matter appeared to be 5 and 6.37 per cent. Hence the average from four specimens is 4.835.

The proportion of sulphur obtained from one of the above specimens was scarcely more than a trace, being only .0165 of 1 per cent. The method of trial does not take cognizance of the sulphur which may be

[ 366 ]

found in the sulphate of lime; nor is this necessary for any purpose of determining the character of the coal, as influenced by the portion of sul-

phur, or rather of pyrites, which it may contain.

The trials for earthy impurity in the two specimens of this anthracite gave 3.22 for the first, and 2.89 for the second—leaving, after deducting these and the volatile ingredients, 92.46 and 93.46 per cent. of fixed carbon. The complete incineration was, as usual, insured by continuing the process for some hours, and occasionally agitating the residue, to expose every part to the action of the air.

The color of the ashes is a light fawn, with specks of pure white.

In burning, during the four trials of this coal under the steam boiler. 3,810 pounds, there were obtained 262 pounds of waste, of which 31.5 pounds, or about 12 per cent., were in the state of clinker; hence it appears that the ashes alone, mixed as usual with fine anthracite, were 6.068, and the clinker 0.326—total, 6.894 per cent. of the coal burned. When the ashes were completely freed from combustible, the residue was but 59.32 per cent. of what it was with the unburnt anthracite remaining; and, when the clinker was also completely reincinerated, it lost 1.455 per cent. Hence the waste withdrawn was made up of ashes 3.6, clinker 0.814, and carbon 2.48—total, 6.894 per cent.

The ashes, as they came from the furnace, weighed 44.03 pounds per cubic foot, and the clinker 30.75 pounds; the former being of a dark gray color, and the latter varying from dark iron-gray to a nearly white color. Many fragments are portions of slate in their original forms, very friable, and having little tendency to cohere. The vitrification is so imperfect as to cause but little clogging of the grate in any of the trials. The total amount of soot and dust withdrawn from the flues after four trials of this coal, was only 3 pounds, weighing at the rate of 17.94 pounds per cubic foot. Of this, 52.63 per cent. was incombustible earthy matter. The trivial influence, or rather absence of all effect of this quantity of dust in impeding the progress of heat through the metal of the boiler, is apparent in the close conformity observable between the first and fourth trials, in regard to the amount of water evaporated by one of combustible matter both trials being conducted with the same damper drawn to the same extent, and with the air plate at the bridge closed. The first gave 11.17, and the fourth 11.20 pounds of water to 1 of combustible matter from 212°.

The reductive power of this coal, applied to the oxide of lead, is expressed by 32.022; 20 grains of the coal having produced 640.44 grains of metallic lead. The ignition of this coal appears to take place with considerable difficulty; having required, on an average, 3.32 hours, from the time the first charge was laid upon the grate, to bring the boiler to the condition of "steady action." The weight of anthracite left unburnt on the grate was 40.18. It should be, however, borne in mind, that no charge of anthracite was laid upon the grate previous to the commencement of firing with wood, as had been done in some trials of the samples already

described.

For domestic purposes, this anthracite is well adapted, both from its high heating power, the small proportion of clinker which it is liable to produce, and from the comparative ease with which the ignition takes place. For smiths' purposes, and for the manufacture of iron, it will present the advantage of a small proportion of earthy matter; and an almost entire freedom from sulphur. A high temperature may probably be found requisite, in order to fuse completely its earthy ingredients,

#### No. 4.

Beach Mountain anthracite, sent by the Delaware Coal Company of Philadelphia.

This sample of coal was accompanied by the following letter from the president of the company, certifying its origin:

"Office of the Delaware Coal Company,
"Philadelphia, September 27, 1842.

"SIR: Enclosed please find a bill of lading, per sloop General Bloom-field, Skinner, for eight hogsheads, containing about three tons of unbroken Peach Mountain red ash anthracite coals, mined by this company below what is called the 'water level,' on one of the seams now worked by it, on a tract of coal land known by the name of Peach Mountain, and belonging to the company, situated about two miles above Pottaville, in

Schuylkill county, Pennsylvania.

"I note these facts as being, according to my recollection of an advertisement of the Navy Department, requested to be communicated with any samples of coal which might be sent to the navy yard, for the experiments intended to be made on the different kinds of coals, to text their relative value for the purpose of generating steam, &c., and for which I respectfully tender the eight hogsheads now forwarded by the General Bloomfield. I shall esteem it a favor to have the results of your experiments on all the varieties which have been forwarded under the invitation of the department for trial, and particularly of the Peach Mountain, when you have had them made.

"I am, sir, very respectfully, your obedient serwant,
"JOHN WHITE, President.

"Beverly Kennon, Esq.,
"Commandant of the Navy Yard, Washington, D. C."

The exterior characters of the Peach Mountain anthracite are—a deep jet-black color; an uneven splintery fracture; a lustre varying from dull to shining, according to the direction in which the fracture is made. Like all the other anthracites, it was wholly unaffected by atmospheric influences in a period of eighteen months, during which they were in my

This sample is more easily separated at the surfaces of deposition than most of the white-ash coals, but less so than that of Lyken's valley. It has no exterior indications of impurity, such as discoloration from oxide of iron, or efflorescences of metallic salts. It has certain surfaces polished and minutely striated, appearing as if they had been subjected to friction under intense pressure. This feature is not, however, of so frequent oc-

currence in this, as in many other samples of anthracite.

Its specific gravity, determined by two specimens, was found to be 1.465 and 1.4632—the mean of which enables us to calculate the weight of a cubic feet of solid coal at 91.505 pounds. But the weighing of 70 charges of 2 cubic feet each in the state of lumps gave 53.7939 pounds per cubic foot, proving that the actual weight in the market is but 0.5878 of the calculated weight in the mine. The same data prove that 41.64 cubic feet of space will be required for the stowage of one gross ton.

In analyzing the two specimens above referred to, the first gave of moisture 1.128, and the second 1.06 per cent.; and of other volatile matter, the first gave 3.272 per cent., and the second 2.56. From these two trials, the total volatile matter is 4.01 per cent.

Another experiment to determine the moisture and volatile matter was made by taking 40 specimens of the coal, (some out of each day's burning,) and from each separating a small fragment; all the pieces being as nearly as possible of the same size. These were then pulverized together, and a quantity of the powder taken for analysis. It yielded of moisture 0.415 per cent., and of other volatile matter 6.55 per cent.—total 6.965.

From 28 pounds of the coal dried in the apparatus attached to the boiler,

the moisture expelled was 1.897 per cent.

100 grains of the second specimen above mentioned gave 0.0062 of a

grain of sulphur.

The total volatile matter obtained by Dr. King from two specimens of this coal was 5.7 per cent. To ascertain the amount of earthy matter in the two specimens, three trials were made on the first; the mean result of which was 6.62 per cent. of reddish-gray ashes. On the second, four incinerations gave a mean result of 6.487. The perfect incineration was secured by keeping the assays in the muffle at a full red heat for more than twelve hours.

On the powdered coal, from forty different specimens above mentioned was made an experiment to obtain the mean amount of earthy matter, which for 80.3 grains of coal showed 5.58 grains, or 6.948 per cent. of ashes of rather deeper color than those from the two specimens above tried. This differs from the mean of those two 0.395 of 1 per cent.

During the six trials of this anthracite for evaporative power, there were burned 7,371.875 pounds; from which the "total waste" was 511.118 pounds, or 6.933 per cent. Of this amount, a pretty large portion was separated in the state of clinker, varying from 35 to 48 per cent. of the whole. The proportion of clinker in this, as in other coals, will be found greater or less, according to the greater or less rapidity of the combustion, as will be apparent from the following table of trials above referred to:

No. of trial.	Total weight of coal burned, in pounds.	Weight of coal burned per hour, during steady action.	Total waste, exclusive of sahes of wood, in pounds.	Weight of ashes.	Weight of clinker.	Ratio of clinker to to- tal waste.	Per centage of the to- tal waste.	Damper through which grace passed to chimney.	Distance damper was drawn, in inches.
1d,	1568.395	103.830	96.922	49.422	47.500	.4911	6.187	Upper	8
<b>3</b> d	1075.825	102.384	75.340	41.145	84.095	.4581	6.993	Upper	8
34	1089.078	89.788	81.858	45.508	36.850	.4562	7.516	Upper	6
4th	939.629	77.928	67.340	43.788	23.552	.3497	7.186	Upper	4
5th	1843.977	91.440	96.731	51.298	44.433	.4593	7.197	Lower	4
6th	1356.976	99.730	93.027	53.572	39.445	.4240	6.855	Upper	

From the above, it will be perceived that, when the coal was burned at the rate of about 104 pounds per hour, the clinker was 49 per cent. of the total waste; and when at 78 pounds per hour, on a grate of the same size,

only 35 per cent.

The total amount of ashes, it will be seen from column fifth, was 284.733 pounds; of which a trial by reincineration proved that 22.01 per cent., or 62.67 pounds, was combustible—leaving only 222.063 pounds of earthy matter. The clinker lost nothing by reincineration, but gained a small per centage by peroxidizing some portions of the magnetic oxide of iron found in the interior of its masses. Hence, the true proportion of earthy matter in this coal, exclusive of the dust which passed into the flues, is +444:444 = 6.083 per cent.; and including that dust, it is 6.1253 per cent. This shows that the analysis of forty specimens gave a residue 0.823 per cent. greater than the combustion of three tons of the coal—a result which may be accounted for by the fact that some dust is lost in the combustion on the grate, which does not happen in the muffle; and that, in becoming fused and vitrified, the hydrated earths lose water, becoming anhydrous silicates. This last circumstance is indicated in the table above given, in which it will be perceived that the three trials which yielded the least proportions of waste, (Nos. 1, 2, and 6,) are those in which the coal was burned most rapidly, and in which the proportion of clinker was also higher than that in the three remaining trials.

The clinker was taken from the grate in large fragments. It was found necessary occasionally to withdraw it during the progress of the experiments, in order to maintain the activity of the fire and the uniform action of the boiler. Its color is dark reddish brown without, and nearly black within. It is thoroughly fused and completely agglutinated into plates. The portions of white slaty and unfused matter adhering to it are much less frequent than in several other samples of clinker which have come under observation. Its weight per cubic foot was found to be 45.12 pounds, while that of the ashes was 58.09 pounds. 6 pounds of dust were found in the flues after the trials of this anthracite, which weighed at the rate of 22.4 pounds per cubic foot, and proved on reincineration to contain

51.75 per cent. of incombustible matter.

It appears from all the above data that the constitution of this anthracite may be taken as follows:

Volatile matter, (from	m 40 s	pecimens)	•	•	•	6.965
Earthy matter, (fron	a the s	ame)	•	•	-	6.948
Fixed carbon -	•	•	•	•	-	86.087
Total	•	•	•	•	•	100.

Its ignition is effected with difficulty—having required, on an average, 3.537 hours at each trial to bring the boiler up to its uniform rate of action. When once ignited, however, the combustion is continued until the greater part of the contents of the grate have undergone incineration. The mean amount of unburnt anthracite withdrawn was only 26.646 pounds; which is only about four-fifths as much as was left of the Lehigh anthracite, one-half as much as of the Lackawanna coal, less than one-half as much as of the Beaver Meadow mine No. 5, and less than one-fourth as much as was withdrawn after using Beaver Meadow No. 3.

It appears that there were left in the waste-

				Per cent. of carbon.

The manner in which this coal acts upon the grate, and the readiness with which its cinder agglutinates itself to bricks and other substances of an earthy nature, will constitute some objection to its use in generating steam.

For use in parlor grates, where a slower combustion is maintained, it will be found to sustain a high character. The synoptical table shows that, in evaporative power, it stands at the head of the anthracite class.

As there was a full sample of this coal, several variations in the mode of conducting its combustion were applied. It will also be observed that ample time was taken to give the fuel an opportunity of showing its power, the first trial having been commenced at 40 minutes past midnight, and extended to 7 o'clock in the evening, and other experiments protracted through many hours of steady action.

TABLE XVI.-PEACH

First trial-upper damper 8 inches open; air plates closed;

The period of steady action to-day is from 8 $\lambda$ , 15m, a. m. to 6 $\lambda$ , 30m, p. m. = 10 $\lambda$ , 5m., during which 31 sets of cheerentians cores. Coal supplied to grate, 1,047 lbs.; water to boiler, 9,238 lbs.

Period of steady action to day, from 7h. a. m. to 2h. 30m. p. m. — 7h. 30m.; coal supplied in that time, 673 lbs.; and 15 sets of observations taken; water supplied, 6,1074 lbs.

#### MOUNTAIN ANTHRACITE.

										<del></del>				
Time each charge was on grate.	Dew point, by calculation.	Gain of temperature by the air before reaching grate.	Difference of temperature between steam and escaping gases.	Water per square foot of absorbing surface per hour.	REMARKS.—Grate surface 14.07 square feet; length of circuit of heated air 121 feet; height of chimney 68 feet.

Anthracite sent by the Lehigh Coal and Navigation Company, Philadelphia.

"Office of the Lehigh Coal and Navigation Co.,

"Philadelphia, July 13, 1843.

"Sin: I have taken the liberty of directing to your address four hogsheads, containing two tons of our coal, that it may be submitted to the experiments now making (I believe under your superintendence) for testing the comparative value for generating steam of different kinds of coal. Our intention in making this shipment, of which a bill of lading is hereto annexed, was recently communicated to you by Mr. Josiah White. When the experiments are consluded, we hope to learn the result from you.

"I remain, sir, yours, very respectfully,

"J. COX, President.

"Prof. W. R. Johnson,
"Navy Yard, Washington, D. C."

The aspect and character of this coal leave no doubt that it will remain for any desired length of time, either under shelter or in the open air,

without material change.

The coal was received generally in lumps, requiring to be reduced in order to be burned advantageously on the grate. Its aspect is that of most of the harder authracites, possessing a deep black color, shining uneven and aplintary fracture, with occasional exposure of conchoidal forms; a striated rather grayish appearance, generally indicative of considerable portions of earthy impurity, marks certain surfaces. The seams of deposition are seldom followed by the fractures.

The specific gravity of two specimens was found to be 1.6126 and 1.5679, from which the calculated weights per cubic foot are 100.79 and

97.99 pounds, respectively, or, on an average, 99.39 pounds.

Thirty-six trials of the weight per cubic foot, in the state in which the coal was received, gave, as will be seen on reference to the tables of trial for evaporative power, 55.316 pounds, or 0.5566 part as much as that computed from the specific gravity of the two specimens.

From the above, it appears that the space required for the stowage of a

ton is  $\frac{2240}{55316}$  = 40.49 cubic feet.

Two boxes of this authracite were reduced to egg size; the first weighed 119.5 pounds, and the second 115 pounds—proxing that the mean weight per cubic foot in this state is 58.625 pounds, or that the grees ton

would occupy only 38.2 cubic feet.

From an inspection of the columns in the tables under the head of "weight of charges of coal," it will be observed that, in a few cases in which the charge box was nearly filled by one or two large lumps, the weight per cubic foot was as high as 60, and even 61 pounds. But a cargo made up wholly of such lumps would not probably weigh much, if at all, more than the average 55.316 pounds per cabic foot, as already obtained. The moisture from specimen a was found to be 2.347 per cent. The trial of this coal for moisture, in the apparatus connected with the boiler, showed no appreciable loss from drying.

The total volatile matter, including water, was found to be 5.235 per

cont. The residue, after incinerating a portion of the first specimen, of which the specific gravity is given above, amounted to 5.065 per cent.

The ashes obtained by analysis are nearly white, or only marked by a

slight grayish tint.

By an inspection of the tables of experiments on evaporation, it will be found that there were burned of this anthracite 3838.25 pounds; and that from all the trials there were obtained of ashes 235.76 pounds, and of clinker 42.25 pounds—total, 278.01 pounds—7.253 per cent. A reduction of the combustible matter remaining in the ashes caused a loss of 26.91 per cent. of their weight—leaving only 171.82 pounds of ashes; and the pulverization and exposure of a portion of the clinker to reincineration at a bright red heat caused a loss of 8.89 per cent., reducing it to 38.49 pounds for the whole amount of coal consumed. By similar treatment, 6 pounds of soot were reduced to 3.156 of ashes. Thus it appears that the true total waste is 213.496 pounds, or 5.562 per cent.

From these data it should seem that the Lehigh anthracite is composed

of-

Volatile matter - - - 5.285 or 5.285

Earthy matter - - - 5.562 or 6.663

Fixed carbon - - 89.153 or 88,052

100. 100.

The clinker of this coal is made up of semi-vitrified matter and fragments of slate nearly white. It is usually in small fragments, and the agglutination is not sufficient to cause much obstruction of the grate. Its weight per cubic foot is only 35.35 pounds; while that of the ashes, including the fine anthracite, is 46.55 pounds for the same bulk, and that of the dust from the flues is 19.51 pounds.

From the table of deductions relative to this coal, the total waste is found to have been on an average 7.2235 per cent. Hence the proportion of combustible matter, which escapes actual combustion and separation

by the sieve, is about 12 per cent.

A trial of this coal, by means of litharge, gave 27.377 times its weight of lead reduced. The combustion is difficult to be brought to its maximum activity, as evinced by the fact that, on an average, it required 3.268 hours from the time the wood was withdrawn from the grate, and the regular charging with coal had been commenced, to bring the boiler to its regular action; and the impracticability of continuing the combustion till the whole of the coal is consumed, is proved by the amount withdrawn after each trial, which averaged 36.125 pounds. The character of the residuum of this coal indicates its adaptation to use in close stoves and furnaces, in which a high temperature is required. There is but a mode-rate quantity of exide of iron, and the other ingredients show but little achdersy to become vitrified.

In the smith's fire, this last-mentioned circumstance would be rather objectionable than otherwise, as it would tend to accumulate cinders in the fire, without affording facilities for their removal—such as a speedy reduction to a fused mass gives to the workman. The analysis of gases from the chimney showed a large proportion of unchanged air—due, in some degree, probably, to the obstruction which the air meets in arriving at the surface of the coal, from the coat of ashes which covers its surface

during combustion.

#### Remarks on the foregoing table of deductions.

Many circumstances appear to indicate that the Lehigh anthracite burns with considerable difficulty—owing, perhaps, in part, to the nature of its incombustible constituents. The length of time required to bring the boiler to steady action, the quantity of coal left unburnt after the fire had become extinct, and the moderate rate of evaporation, together with the low evaporative efficiency of the coal, and especially with the large quantity of oxygen found on the fourth trial in the gases escaping to the chimney, all tend to demonstrate the want of a vigorous and casy combustion. To these circumstances may be added the fact, that, when in the second trial the air plate at the furnace bridge was open, in order to give an increased supply of air to the products of combustion, the effect was to diminish, instead of increasing, the evaporative efficiency of the pound of coal. In the 41st line, it appears that with the air plate closed, as in the first, third, and fourth trials, the steam from water at 212° produced by 1 of coal, was, on an average, 9.073; while in the second, it was but 8.509; indicating a loss of more than 6.2 per cent. Nor is this difference attributable solely to the difference in amount of waste matter found after the several trials; for it will be observed in the 43d line, that when allowance was made for this circumstance, the water from 212° to 1 of combustible matter, was on the

First trial - - - - 9.6476
Third trial - - - - 9.9207
Fourth trial - - - - 9.7986

And the mean - 9.7589
While for the second it was 9.2288—the difference being still 5.4 per cent.

of the larger number.

The very close approximation in the above numbers for the first and fourth trials was given notwithstanding the difference in the size of the grate in the two cases, its area having been 14.07 on the former, and 16.25 on the latter day of trial. The accordance was given also even with the wide disparity of draught in the chimney on the two days—the syphon having stood on the first at 0.3714, and on the fourth day's trial at 0.4458 inch. The superior force of draught is explained in the way already indicated, by a remark at the commencement of experiments in table XXVI, where it is stated that the weather was clear, and the wind brisk from the The two circumstances of a stronger draught and a larger grate surface occasioned the evaporation of 15.33 cubic feet of water per hour during the fourth trial; while only 10.93 cubic feet were expelled in the same time during the first experiment. By a reference to table CXCIV, it will be seen how large a portion of all the heat developed by this coal was expended on the gaseous products of combustion. That table will also afford the means of determining how nearly the total evaporative power of the Lehigh anthracite approaches to that of other coals of the same class, when all the absorbents of heat are brought into the computation.

No. 6.

Anthracite from the Lackawanna coal region, Euzerne county, Pennsylvania, forwarded by the Delaware and Hudson Canal Company.

No certificate of origin accompanied this sample of coal, but only a bill of lading, indicating by whom it had been sent. The quantity was ex-

actly 4,480 lbs., or two gross tons, as certified in the bill of lading.

The characters of the coal are, in general, a deep jet-black color, except on the surfaces of superposition, on which the usual deposites of mineralized charcoal are seen, and occasionally in the natural partings, technically called "cleats," which appear to be formed by thin laminæ of the earthy ingredients of the coal: these appear to be, generally, sulphate of lime; sulphuret of iron is scarcely discernible on the surface. The fracture is uneven, and semi-conchoidal, except in the direction of the main cleat.

This coal undergoes no change by an exposure of twenty months to varying states of atmosphere. Its specific gravity, as determined by the mean of two separate trials, was found to be 1.4213; which would indicate that, in the solid state, as it exists in the mine; the weight of a cubic

foot is 88.83 lbs. avoirdupois.

In the state of marketable lump coal, in which it came to hand, the weight, as determined by forty-four trials in the charge box, was 48.886 lbs. per cubic foot, or .5502 of the above calculated weight. This, together with the variableness of the charges, in regard to weight, will be understood by reference to the column headed "weight of charges of coal." From the numbers there given, it will be seen that the highest weight of any one charge was 108 lbs., or 54 lbs. per cubic foot; and the lowest 90.5 lbs. per charge, or 45.25 lbs. per cubic foot; and that the mean of these two extremes differs in excess from the above general mean, only about three-quarters of a pound. From these facts, it appears that the space required in the bunkers of a steam ship for the stowage of one ton of 2,240 lbs. of this anthracite, is 45.82 cubic feet.

In: analyzing this coal, the moisture expelled by a temperature of 216° was, in one case, 1.382, and in another 1.174 per cent.; or the mean was = 1.276 per cent. A heat of full ignition expelled in addition, from the same specimens, a mean of 5.087; showing the total volatile matter to be

= 6.365 per cent.

Four trials on each specimen, by incinerating them in platinum capsules placed for some hours in the open muffle of an assay furnace, left of earthy matter for one specimen 4.84, and for the other 4.47 per cent.—mean, 4.655. The sum of the volatile and earthy ingredients deducted from the total weight, for ascertaining the combustible fixed carbon, gives 68.98. On one of the specimens above referred to, was made a trial to ascertain the proportion of sulphur; which resulted in giving 0.1226 of one per cent. On two other specimens of this coal, Dr. King made trials to determine the quantity of matter volatile at redness, which resulted in giving for one 6.85, and for the other 4.875 per cent., or a mean of 5.462.

While prosecuting the experiments on evaporation, 45.53 lbs. were placed in the steam drying apparatus, where it remained for about 48 hours, most of the time surrounded by steam a little above the temperature of 212°: during that time it lost 15.5 ounces, or 2.18 per cent. The coal

[ 386 ] 106

used in this trial had for some time previous been exposed to a temperature not exceeding 50° Fahrenheit, and the size of lumps was from three to four inches in diameter.

A trial of 18 grains of this coal intimately mixed with 800 grains of litharge, and covered with a portion of pure litharge, effected the reduction of 568.86 grains of lead, or 31.603 times the weight of coal used. This trial was made on a specimen of which the moisture and earthymatter had been found to be 5.656 per cent.; and consequently the quantity of matter truly combustible, by which the reduction was effected, was 16.982 grains: from which it appears that one part of the combustible matter of this coal reduced 33.49 parts of lead. And as it is known that one part of pure carbon is capable of reducing thirty-four parts of lead, it seems that the reductive or "heating power" of this combustible, as deduced from this test, differed from that of pure carbon by only 1-68th part.

The character of the residua of this coal, procured by analysis, is that of a dense white or slightly grayish ash, of which the per centage is given

above.

From the column of "remarks" in the accompanying tables, the proportion of waste derived from actual combustion will be seen to vary in the different trials, from 7.276 to 10.694 per cent. The total amount of askes, mixed of course with a certain proportion of fine particles of unburnt anthracite, such as passed the meshes of a sieve three-tenths of an inch in diameter, was 318.95 pounds; and that of the vitrified portion, or clinker, was 52.07 pounds; both derived from the combustion of 4112.51 pounds of anthracite. Hence it appears that the ashes are 7.741 per cent., and the clinker 1.266 per cent. of the coal actually burned in the manner described in the tables. The ashes weighed 50.95 pounds per cubic foot, the clinker 36.88 pounds. Five pounds of soot and dust from the flues, left 3.264 pounds after complete incineration.

The clinker is very imperfectly vitrified, agglutinating, and often cover-

ing portions of nearly pure white argillaceous matter.

In order to ascertain what proportion of the ashes was really combustible, a quantity was reduced to fine powder, and a weighed portion exposed on a platinum capsule, in an open muffle, to a bright red heat for several hours, occasionally agitating it to expose every part to the access of air: the result was, that 34.555 per cent. of the whole was combustible; or of the 7.741 per cent. of ashes, 5.066 only were actually incombustible. The ashes thus finally obtained were of a nearly chocolate brown, showing that the specimens above analyzed did not properly represent the general mass of this anthracite, in regard to the color of its ashes.

Having reduced a portion of the clinker also to very fine powder, it was in like manner exposed for some hours to bright ignition, to ascertain whether any portions of anthracite had been retained in the interior of its mass, and had thus escaped combustion. The result was an actual gain, instead of a loss of weight. This gain, amounting to 0.55 of one per cent of the substance tried, was doubtless due to a conversion of some portion of protoxide into peroxide of iron, the powder having been observed to be partially magnetic before calcination, but not so afterwards.

In the ashes and clinker above reduced, there were contained for the four trials of this coal, 2.647 pounds of wood ashes, derived from the wood employed in raising temperature. This amounts to almost exactly one per

cent. of the total waste, after deducting the unburnt anthracite of the ashes, as above stated. Hence the analysis of about 4,100 pounds of Lackawanna anthracite yielded 6.346 per cent. of incombustible matter, of a reddish-brown color, instead of 4.655 per cent. of a white or grayish-white ash, as afforded by the analysis above presented. The difference in color is accounted for by the known fact that the sulphuret of iron, which is the cause of redness, is often very irregularly distributed through the mass of a coal bed, and its accompanying slates. Specimens may chance to be selected for analysis which are almost wholly free from that

ingredient.

The time required for bringing the boiler to steady action by this coal was, in the several trials, 0.75, 45, 2.5, and 2.91 hours; or, on an average, 2.666 hours. The quantity of anthracite left upon the grate was, by a mean of the four trials, 57.19 pounds. The use of this coal in a grate for domestic purposes, will be but little different from the mean action of red ash coals in general. The considerable quantity of water it contains causes it, when suddenly thrown on a mass of highly ignited coal, to decrepitate with considerable force; but in this it was not observed to surpass several other samples of the same class. It corresponds well in this particular with the Lackawanna anthracite used by many of the steamers on the New York waters, which I have observed, while driven with a strong artificial blast, to emit copious showers of fine particles from the chimney tops, speedily covering the deck and all other objects on which they could rest. A more moderate draught would avoid this inconvenience and loss, but would demand a considerable increase of furnace room to effect the requisite amount of combustion, and supply the necessary quantity of steam.

Being among the earliest in the series of experiments, the first and second trials will be found to lack the observations on the wet bulb ther-

mometer, and those of the attached thermometer.

TABLE XXX.—LACK

Third triul-upper damper 10 inches open; air plates closed;

The period of steady action this day extends from 9h. 5m. a. m., when the fifth charge was all on the grate, to 4h. 45m. p. m., when the thirteenth and last charge was on, — 7h. 49m, 1 goet supplied, 799.5 lbs.; water, 7,226 lbs.; sets of observations taken, 15. By these data, the water to 1 of coal is 9.088, whilst the final result (as seen in the table of deductions) is 8.587. The excess of the former over the latter number, is probably attributable to the large amount of coal put on the grate in the early part of the experiment, before the period of steady action commenced, and which doubtless exceeded the quantity on the grate at the time the period of steady action terranated. Such differences must inevitably occur, since the eye only can be relied on to judge of the quantity remaining unburnt at any given moment.

#### General remarks on the preceding table of deductions.

It appears that with a chimney 41 feet in height, as in the first and second trials of Lackawanna coal, and with the damper drawn so as to give free exit to the gases as rapidly as they would pass the two interior 10-inch flues, the rate of evaporation was from 8.85 to 12.48 cubic feet of water per hour. After the chimney had been raised to 63 feet in height, the rate of evaporation on the third trial, when the damper was drawn 10 inches, was 15.08 cubic feet per hour; and on the fourth, when it was opened but 5 inches, the rate was 11.27 cubic feet. Notwithstanding these considerable differences in the rate of evaporation, with variations also, as seen in the third line of the table, in the area of the grate, and in the opening, closing, or removal of the air plate at the furnace bridge, as given in the 46th line, the accordance in the results of the four trials found in the 40th, 41st, and 43d lines, is as near as could reasonably be expected from the operations of combustion. In the second experiment the grate was placed within 7 inches of the bottom of the boiler, and the result of that trial is about two per cent. higher than the general average, as shown That was, however, found too near for convenient manin the 43d line. agement, and the distance of 9 inches was resumed after one or two trials. It is important that the fireman should be able to observe, especially in burning anthracite, that all parts of his grate are uniformly well covered with fuel. If large holes are allowed to exist in some parts, while heavy accumulations of coal remain on others, both may become sources of loss; the one by allowing unburnt air to pass, and the other by forming carbonic oxide, which may in part escape subsequent combustion.

In the table (CXCIV) of experiments on the composition of gases from combustion will be found some indications of the differences which exist in the action of a furnace while using the same kind of fuel. It will also be perceived that on the fourth trial of Lackawanna coal, the heat employed on the air required for the combustion of a pound of coal was equal, in evaporative power, to convert about nine-tenths of a pound of water at 212° into steam of the same temperature. With respect to the anthracites generally, it may be said that their combustion is effected solely by the contact of air with the surfaces of their solid masses. the case of bituminous coals, on the contrary, the air which supplies combustion is inevitably intermixed, during its passage through the fire, with much fuel in a gaseous state. The existence, therefore, in an anthracite fire, of passages or "blow holes," through which considerable currents of air can pass without bringing every atom of it in contact with a lump of fuel, is an almost sure source of loss of useful effect. In the bituminous coal fire, the want of such openness, to allow sufficient air to effect the complete combustion of the gaseous products, has given rise to the many inventions for preventing smoke, and burning more completely

the gaseous products of the fuel.

#### No. 7.

Anthracite from Lykens valley, Dauphin county, Pennsylvania, sent by the Lykens Valley Coal Company.

This sample of coal was accompanied by the following letter to the President of the late Board of Navy Commissioners:

"BALTIMORE, July 23, 1842.

"Dear Sir: At the request of the Lykens Valley Coal Company, we forward to you for trial three hogsheads of coal from their mines. It is from vein No. 1, seven feet thick, and has been mined four weeks; can be delivered at any point on the Atlantic coast, from the Chesapeake bay, which it reaches through the Pennsylvania and Tide-water canals. You will please communicate the result of your trial of it to us.

"Your obedient servants,

"J. WHITEFORD & CO.

#### "Commodore WARRINGTON."

The exterior characters of this anthracite are very nearly related to those of many bituminous coals. Its fracture is uneven and splintery, except where the main cleats or partings are exposed. It differs from most of the anthracites already described, in the circumstance of having the surfaces of deposition often exposed in the fractures, displaying copious deposites of carbonaceous "clod," or mineralized charcoal, preserving the vegetable forms from which it was derived. In these and many other characteristics, it strongly resembles many samples of the anthracite of South Wales, which have fallen under my notice.

Two specimens were tried for specific gravity: the first gave 1.3828, and the second 1.3954. The mean weight per cubic foot of solid coal in

the mine will hence be 86.82 pounds.

Twenty-six trials in the charge box gave the mean weight per cubic foot, in the state in which it was received, 48.558 pounds—showing that the actual is 0.5591 of the calculated weight. This proves that the space required for stowing one gross ton is 46.13 cubic feet. The greatest weight in any charge was 106, and the least 91 pounds—the mean of which gives 49 pounds per cubic foot.

Two boxes of this coal were reduced to egg size; in which state one weighed 93½, and the other 96 pounds—showing the average weight per cubic foot to be 47.375 pounds, or 1½ pound less than the average weight

above stated.

The moisture expelled in analyzing the two specimens above mentioned was 0.707 and 0.785, respectively; and the portion expelled from 28 pounds placed in the drying apparatus of the boiler was only half an

ounce, or 0.111 per cent.

On exposure to a bright red heat in a closed platinum crucible, the first specimen lost, in addition to its moisture, 6.263; and the second 5.874 per cent.—showing that the mean amount of volatile matter is 6.314. Two specimens tried by Dr. King yielded a mean of exactly 7 per cent. of volatile matter, including moisture.

The proportion of sulphur found in the first of the above specimens is

[ **386** ]

0.091 of 1 per cent —a quantity which can certainly be of little consequence to the character of the coal.

Analyses of the two specimens above mentioned gave of earthy matter

5.4 and 5.66 per cent. of the weight of raw coal.

This gives the composition as follows, viz:

Volatile matter	-	-	-	4 +	-	- 6814
Earthy matter	-	-	•	-	-	- 5.530
Fixed carbon	-	-	-	-	-	- 87.656
						100.

The ashes obtained from these analyses are of a fawn color, slightly

coherent, bulky, and but moderately gritty, resembling fine clay.

From the accompanying tables of experiments, it will be found that there were consumed in the three trials of this anthracite 2,471 pounds; from which were derived of ashes 189.798, and of clinker 109.75; or the total amount was 299.548 pounds. Hence the per centage of waste is 12.123.

lers are mostly reddish brown, with yellowish-white portions, s, even in the parts where the vitrification is most perfect. e slaty fragments have undergone no fusion. The ashes are y, and weigh 52.06 pounds per cubic foot; while the clinker

32.75 pounds.

es contained 36.8 per cent, of unburnt anthracite, and the 9 per cent. Hence the true amount of earthy matter in the 39.798—69.845 == 119.953 pounds; and that in the clinker is 745 == 108.005 pounds. There were obtained of soot and dust from the flues, after three days' burning of this coal, 12 pound; of which, the density was such, that 21.56 pounds would have been re-

which, the density was such, that 21.56 pounds would have been required to make 1 cubic foot; and of this mixture, experiment proved that 37.6 per cent., or 0.657 of a pound, was earthy matter, almost identical in characters with that of the ashes. From all these sources, we get the preportion of earthy matter from this coal equal to

= 9.252 per cent., instead of 5.53, as given by the above analyses. It also appears that 12.123—9.252 = 2.871 per cent. of the coal escaped

combustion and separation by the sieve.

In no instance was it found necessary to lay a charge of this anthracite upon the grate, in order to secure a speedy ignition after the wood was withdrawn. The mean time required to bring the furnace to steady action was 2.127 hours; only three-fifths as long as the average time required by the Lehigh, Beaver Meadow No. 3, Forest Improvement, and Peach Mountain anthracites.

The average amount of unburnt anthracite withdrawn after each trial was but 18 pounds; while the mean amount for the four samples just named was 53.83 pounds, or almost exactly three times as much. Both these circumstances indicate the approximation of the Lykeus valley authracite to the class of free-burning bituminous coals.

The first specimen above analyzed, when tested by oxide of lead, yielded 31.155 times its own weight of metallic lead. Deducting the moisture-

maining or combustible portion = 93.893 per cent.; hence  $\frac{100\times81.155}{98.893}$  = 33.181 = the reductive power of the combustible constituents of this coal.

In an open grate, this anthracite gives a quick, lively, and cheerful fire; but lacks the durability of several other samples. The proportion of fused cinder, or clinker, to the total waste being 37.5 per cent., it will not answer well for use in close stoves, heating furnaces and other apparatus, in which entire freedom from all tendency to produce slag and to clog the grate, is a property so much desired.

In blacksmiths' forges, cupolas, and smelting furnaces, it must doubtless be found to work easily, yielding an intense and rapid fire. For reasons

already stated, no trials of it were made in the smith shops.

This coal breaks easily into small sizes; burns very freely, with considerable flame, but without any characteristic appearances of caking coals, and preserves the definite forms of its masses, except when it disintegrates

during ignition into small angular fragments.

Its action under the steam boiler was highly satisfactory. Its considerable portion of volatile matter, which burns with a clear yellow flame, of moderate length and brilliancy, without the slightest appearance of smoke, and without requiring a very powerful draught to sustain and quicken the combustion, gives it a decided advantage for avoiding that waste which arises from a violent artificial blast.

Closed.	-	It appears from line 43 that the open air plate proved beneficial
U. 4		to this coal, so far as evaporative efficiency is concerned; but
}		from lines 20 and 21, it does not appear that the boiler acted so rapidly on the second as on the first day's operations.

[ 386 ] 130

#### Remarks on the foregoing table of deductions,

The results of the three trials of Lykens valley anthracite prove, that on the first day, when 112.43 pounds of coal were supplied to the grate per hour, the rate of evaporation was 13.75 cubic feet of water per hour, and that the final result of water to 1 of coal, from 212°, was but 9.076.

The air plate at the furnace bridge was closed. At the next trial, the plate was half uncovered, admitting air through six rows of its apertures. The rate of supplying coal was then only 76.22 pounds per hour, and the evaporation 13.03 cubic feet of water per hour. On that occasion the water from 212° to 1 of coal, was 10.067—being a gain of rather more than 11 per cent. This was the highest result obtained with the coal under consideration. It appears that on the third trial, with the air plate closed and the damper drawn but 4 inches, the evaporation was reduced to 11.89 cubic feet per hour; while the coal supplied was 103.41 pounds, and the water to 1 of coal, from 212°, in the final result, was 9.245. In line 13, it will be seen that the amount of waste on the three several days of trial was 10.025, 11.597, and 15.114 per cent., respectively.

These facts point to the necessity of conducting the combustion of this anthracite either with a small supply of air thrown in above the ignited

mass, or with only a thin stratum of coal upon the grate.

It will be seen, on reference to the 15th line of the table, that, on the first trial, the vitrified portion of the waste matter was 48 per cent. of the whole, and but 26.7 per cent. of it on the third. This again confirms the position already laid down relative to the action of a rapid combustion, and a consequent high temperature, in determining the vitrification of earthy materials. The facility with which these materials are fused would, in the case of employing this anthracite for the smelting of iron, afford the advantage of a ready conversion into cinder, creating no additional demand for flux, and requiring no great elevation of temperature for that purpose.

From lines 29 and 30, it appears that the air, in traversing the chambers between the double walls of the furnace, and passing under the fire flue, became heated to an average temperature of 263°, and that the products of combustion left the boiler at 265°, or about 34° higher than

the contemporaneous temperature of the steam in the boiler.

From the 39th line of the table, it is apparent that, on the second trial, with six rows of apertures in the air plate open, the gases escaped from the boiler with nearly twice as much excess of temperature above the steam as on the preceding day, when the whole remained closed. This fact, together with the superior evaporative effect already noticed, appears conclusive as to the advantage of a supply of air thrown in above the fuel.

From the average in line 42, it is evident that 1 cubic foot of this anthracite evaporated nearly 460 pounds of water from a temperature of 212°; the lowest result being 438, and the highest 489.

No. 8.

Beaver Meadow anthracite—part of a stock procured for use in the U.S. Steamer Union.

This coal had so near a resemblance to the samples of Beaver Meadow coal sent for trial by the company, that little needs to be said in relation to its characters. It was broken to a pretty uniform size of lumps of about 4 inches in diameter; and the weight of 1 cubic foot was, on an average, 55.084 pounds. This will show that 40.65 cubic feet of space are required to stow 1 ton.

It was with coal of this sample that were afterwards made the experiments of mixing and burning together, in one case, bituminous coal of the Midlothian (Virginia) mines, and in another, that of Cumberland in Maryland, in the proportions by measure of one-fifth bituminous to

four-fifths anthracite.

There were two varieties of this anthracite landed at the yard nearly at the same time, and thrown in two separate heaps. The coal for one day's burning was taken from each heap. By reference to the table of deductions following those of the experiments, and a comparison of the results which it furnishes with those found at pages 45 and 61, and which relate to the two samples sent for trial by the Beaver Meadow company, it will be seen that the coal now under consideration was 4.86 per cent. inferior in evaporative effect to the mean of those samples.

## FROM TABLES XXXVII, XXXVIII.

ànthracite coal, from navy yard.

Remarks.
The large amount of coal left on the grate is attributable, in part, no doubt, to the deficiency of draught; but by reference to page 45 it will be seen that the Beaver Meadow sample, from slope No. 3, gave, on an average, 112.37 pounds; almost identical with that found on the first trial here recorded.
•
No observations on this subject taken at this period.
The height of chimney-(41 feet) was probably too low to give the most useful effect to this coal.  (Observations for this deduction not taken.)

#### No. 9.

"Natural coke," from Tuckahoe, Virginia, sent by Messrs. Barr and Deaton.

The following letter relates to this sample:

"RICHMOND, July 1, 1842.

"DEAR SIR: Annexed you have a receipt from Captain Shorter, schooner Presto, for two tons natural coke, (all lumps,) to be tested as fuel for war steamers. It is from a mine just opened on Tuckahoe, Virginia.

"We were advised by Mr. F. B. Deane, whom you know, to forward this thus late—knowing it to be a new article, and believing you would, at your leisure, give it a trial, should it not arrive in time for the general test. The heat from it is intense, and it answers well in our pit engines.

"Yours, respectfully,

"BARR & DEATON.

"WILLIAM B. Scott, Esq."

The exterior appearance of this material is very different from that of any of the anthracites heretofore described, and equally or more so from that of all the bituminous coals which will hereafter come under notice. It is of a uniformly dull black, or merely glimmering lustre; the surfaces of deposition appearing in many specimens to be distorted, or almost wholly obliterated. In others, fractures occur along those surfaces; but the fossils which, in coal, usually occupy those spaces, are nearly undistinguishable. The spaces are found occupied, in a great measure, by sulphate of iron. This substance gives rise, during the combustion, to the development of sulphurous fumes excessively oppressive to the organs of respiration. There appears to be scarcely more regularity of form in the masses of this material than in those of common anthracite. When reduced to powder, it becomes perfectly black, and the streak on white earthenware is of the same color.

One specimen (a) of this material had a specific gravity of 1.305; another (b) 1.3413. The mean of these gives the calculated weight per cubic foot 82.695 pounds.

Forty-seven experiments proved the actual average weight per cubic foot to be 46.635 pounds; the highest being 54.75, and the lowest 40.5. Hence the ratio of the actual to the calculated weight is 0.5639: 1. The space required per ton is 48.032 cubic feet.

The moisture expelled in drying a at 216° was 0.962, and that from b, 0.775. 28 pounds exposed for four days in the steam drying apparatus lost

1.116 per cent.

Of other volatile matter, a lost by mean of two trials 10.428, and b 14.045. The sulphur procured from b was 0.466 per cent. The total volatile matter obtained from one specimen tried by Dr. King was 18.916, and that from another 12.25. The mean of these is 13.105; while the mean of the two above stated (including moisture) is 13.083.

Of earthy matter, specimen a gave, by a mean of four incinerations, 10.991; and by four others, 11.15—mean 11.07; b gave 2.44 and 3.07, or a mean of 2.755 per cent. The higher numbers in both of these cases are probably due to the more complete peroxidation of the iron in one set of trials than in the other.

Onring the experiments on evaporation, there were burned 4,209 pounds of this coke, from which were obtained 551.5 pounds of ashes, weighing 56.98 pounds per cubic foot; 225.75 pounds of clinker, weighing 38.25 pounds per cubic foot; and 11.5 pounds of soot and dust from the flues, weighing at the rate of 22.67 pounds per cubic foot. Of this latter material, the carbonaceous portion was doubtless due almost entirely to the wood used in heating up the boiler. A reincineration left of the

Ashes - - 52.78 per cent, incombustible.
Clinker - - 90.37 "
Sout - - 46.66 "

Hence the absolutely incombustible matter in the state of

```
Ashes, is - - - 291.080 pounds.

Clinker - - - 204.105 "

Dust or soot - - - 5.366 "

Total - 500.551 "
```

From this deducting the ashes of 905.2 pounds of wood = 2.777 pounds, we have left 497.774 pounds = 11.826 per cent., or 4.914 per cent. more than the mean of the two specimens above analyzed.

The data furnished by the analyses show that the two specimens had

the following constituents:

T. C. Carre				Specimen a.	
Moisture -	-	-	•	0.962	
Sulphur -	•	•	-	(not tried)	
Other volatile ma	tter -	•	-	10.428	
Earthy matter	-	-	-	11.070	
Fixed carbon -	-	-	-	77.540	
			-		_
				100.	Ì

100, 100. Volatile to fixed combustible 1:7.435 1:6.068

The operations on a large scale afford the following, viz:

```
Moisture, from 28 pounds - - 1.116 per cent.

Other volatile matter, from four specimens - 11.977 "

Barthy matter, from 4,209 pounds - - 11.826 "

Fixed carbon, by difference - - 75.081 "

Volatile combustible to fixed carbon - 1:6.2688
```

The clinker of this fuel is externally of a reddish-brown color, black on the interior, tending to apread into continuous masses, but not seriously impeding the grate. In one instance, however, it was found necessary to remove a portion, to maintain a uniform action of the boiler. An oppressive eder of sulpharous acid, evidently derived from the decomposition of the sulphate of iron, was the consequence of expessing this clinker while hot on the open hearth of the furnace.

[ 386 ] 140

Among the soot and dust of the flues, withdrawn after burning this coke, was found a considerable quantity of sulphuric acid; 157.9 grains of the dust being digested at a temperature below boiling point for twenty hours, and then filtered, was found to contain free sulphuric acid. Chloride of baryum afforded a precipitate of sulphate of baryta, which, being filtered out and ignited, weighed 22.9 grains—showing the sulphuric acid to be 4.98 per cent. of the weight of dust assayed. The presence of this material in so considerable quantities must doubtless prove highly injurious to the metals with which it comes in contact.

Of specimen b, 20 grains treated with litharge yielded 626.88 grains of metallic lead, or 31.344 times its own weight. Deducting moisture and

earthy matter, the lead to 1 of combustible is 32.491.

The trial of this coke in an office grate exhibited the following phenomena: When laid on a bed of ignited coke, it remained for twenty or thirty minutes with little or no emission of flame. It then began to yield a portion of blue flame, which, as the heat increased, passed into a yellowish white, intermixed with blue, and rising to the height of 12 or 15 inches. This character of affording a pretty long flame had been noticed in the experiments on evaporation.

This fuel burns with about the same activity as Lykens valley anthracite. On becoming fully ignited, it throws out an intense heat, accompanied with the blue flame of an anthracite fire. Being more porous than the latter, and exposing more surface to the action of the air, it burns more rapidly, and with proportionate intensity of heat. By projecting a little water on the ignited mass, the blue is changed to a crimson-colored

flame.

This coke would be more suitable for hall stoves and house-heating furnaces than for open grates, especially if the former were so constructed as to confine the strong sulphurous fumes.

The time required to bring the boiler to steady action was 1.745 hour, or about # of an hour less than was required by the Lykens valley an-

thracite.

The quantity left unburnt at the conclusion of each experiment was 43.687 pounds. The very large proportion of combustible matter found in the ashes by reincineration (47.22 per cent. of their weight) indicates that a rapid disintegration occurs during the combustion. This effect rendered it frequently necessary to replace the contents of the ash pit on the grate,

in order to secure a satisfactory combustion.

It cannot be recommended for use in smiths' fires, owing to the large amount of sulphur, and the high proportion of earthy constituents. With a very slow rate of combustion, which would leave a large portion of its residue unvitrified—such a rate, for example, as is used in Cornwall, where the water evaporated by a square foot of absorbing surface is but about nine-tenths of a pound per hour—this material would afford a steady durable heat, with but little impediment to the passage of air through the grate.

A reference to the deductions table XLIV, will show that, on an average, as seen in line 26, it took 8.34 pounds of coke to evaporate 1 cubic foot of water, and that the cubic foot of coke evaporated from 212° 395.3 pounds of water, while the same bulk of Lykens valley anthracite, to which its action bears a stronger analogy than to that of any other of this class, produced 459.6 pounds of steam.

In line 39 of the table of deductions, it will be seen that when the air plates at the furnace bridge were open, the gases passed to the chimney at a mean temperature above that of the steam, for the two days on which that arrangement was adopted, of 46°.74; while on the two days when the air plate was closed, the mean excess of temperature was only 38°.5. This, as well as the slight superiority in evaporative effect observed in the 43d line, when the air plate was open, led to the conclusion that some portion of combustible gases escaped combustion when the air plate was closed.

No. 19.

Artificial coke from Midlothian coal, procured for use in the navy yard.

This fuel was produced by coking in a pile, on an open coke hearth, at the navy yard, 16,190 pounds of coarse, and 6,090 pounds of fine Midlothian coal; the latter being used as a covering for the former, which was piled loosely together, in an oblong pile 15 or 20 feet long, 6 feet wide, and 4½ high, with suitable air passages leading to chimneys formed at three points in the length of the heap. The coking process was conducted slowly, lasting fifteen days. This was intended to avoid the waste of any portion of fixed carbon, and to yield a coke which, though it would undergo no further change of form while in combustion, would

still give a flame of some activity.

From the above amount of 22,280 pounds of coal, there were iderived 14,045 pounds of coarse and 3,870 pounds of fine coke. Had the coarse coke been to the whole weight only in proportion as the coarse coal was to its whole weight, there would have been 13,018 pounds in the coarse state. This proves that 1,017 pounds of coarse coke had been produced out of the fine portion of the coal. The loss of weight on the whole was 4,265 pounds, or 19.14 per cent. The finer portion round the edges of the heap, and some few lumps near its exterior, had of course escaped in part the full effect of the coking. But the purpose had been completely attained, producing a fuel of great strength and activity, and adapted to purposes for which the coal out of which it was formed would be inadmissible. During the coking, a considerable quantity of tarry matter, with some sulphur and other products of the distillation going on within the heap, were condensed about the chinks of the clay covering placed on the exterior. Flame was perceived but for a short time during the operation; and I am inclined to think that as much economy in conducting the process was observed as would be found practicable with coal of this character.

The weight per cubic foot of this coke, as determined by sixteen trials, was 32.734 pounds. The average weight of Midlothian "screened" coal was found to be 45.722 pounds; that of the "average" 54.044 pounds; and as the coarse and fine portions employed to form the coke were respectively 72\frac{2}{3} and 27\frac{1}{3} per cent., if the weights in a cubic foot of the mixture employed be assumed to have been proportionate to these numbers, then will the coarse coal in a cubic foot be 0.7266 \times 45.722 = 33.924 pounds; that of fine, 0.2733 \times 54.044 = 14.806 pounds; which makes the cubic foot 48.03 pounds; deducting 19.14 per cent., there are left 38.837 pounds; and from this, taking the weight of a cubic foot of coke, 32.734 pounds, there is left 6.103 pounds. Hence the enlargement of the bulk by coking was 6.103 \div 32.734 = 18.369 per cent.

The space required for stowing 1 ton is 68.495 cubic feet. The coke lay some time on the ground after being raked from the heap, and a rain fell, which caused a complete saturation with moisture; \$0 pounds lost by two

days' exposure in the drying apparatus 9 ounces, or 2.81 per cent.

The total weight burned was 1,037 pounds; and the weight of ashes withdrawn (exclusive of those from wood) was 61.82 pounds; that of clinker 109.75 pounds. Hence the total waste is 171.57÷10.37=16.545 per cent. of the coke actually burned.

From the Midlothian screened coal, the total waste was 10.31 per cent.; and from the average coal of the same mines, 14.32 per cent. Hence the waste (ashes and clinker) from 100 of the mixture of these two; formed as was that which was subjected to coking, would have amounted to 13.567. As the coal lost 19.14 per cent. in coking, the remaining 80.86 parts by weight of coke had also 13.567 parts of earthy matter, which is 16.778 per cent. One pound of soot and dust was procured from the flues after burning this coke.

It took two hours to bring the boiler into steady action, from the time the charging with coke commenced. When once ignited, it burns with

great freedom and rapidity.

Upon a comparison of evaporative powers, after making in both cases the proper deductions for earthy matter, it will be found that this coke gave 10.343, and the screened and average Midlothian coal 9.85 pounds of steam from water at 212° to 1 of combustible matter. This proves that the fixed carbon contained in this coke had, weight for weight, a higher evaporative power than the volatile ingredients of the coal which had been expelled in coking. The superiority of the coke combustible over the coal combustible is 5.005 per cent. of the evaporative power of the latter.

From the column of "remarks" in the following table, it will be observed that it became necessary in the course of the experiment to withdraw from the furnace a quantity of clinker, in order to allow the combustion to

proceed with regularity.

REMARKS.—This coke will be observed to give a greater rapidity of evaporation than most of the coals tried during these experiments. The porougness of coke, and the compactness of anthracite, place them in strong contrast in regard to facility of combustion, and justify the preference of the former facility for locomotive engines; while its bulkiness precludes its adoption for sea steamers.

The great activity of this fuel rendered it necessary to load the valves with extra weights, to obviate foaming, and discharge of water mechanically mixed with the steam.

#### No. 11.

#### Artificial coke from Neff's Cumberland coal.

The coke on which this experiment was made was part of a quantity produced under my direction from a portion of the same boat load of coal from which the sample of Neff's coal, hereafter to be described, had been taken. It had lain for several weeks in the yard, and was doubtless, when taken to the coking hearth, quite as fully saturated with moisture as the sample tried for evaporative power. By reference to the description of that coal, it will be seen that, in the drying apparatus connected with the boiler, it lost 2.455 per cent.

The coke heap was composed of 22,340 pounds of coarse and 6,160

pounds of fine coal.

After coking for ten days, it was drawn, and, without being exposed to any rain, was carried while yet moderately warm, reweighed, and housed.

The quantity burned under the boiler was taken immediately to the building containing the apparatus, and was used on the following day.

This statement may indicate that the coke contained the minimum of moisture—contrary to what happened in the case of the coke from Midlothian coal, which contained, as proved on trial, 2,812 per cent. of moisture.

The weight of coarse coke from the above quantity of coal was 16,770 pounds, and the fine 6,805. Hence the weight of coarse coke is 75.065 per cent. of the coarse coal; while the whole weight of coke is of the whole weight of coal, both coarse and fine, 82.719 per cent.—showing a loss of 17.281 per cent., and proving that the disintegration of the coarse, rather than the agglutination of the fine portions of the coal, was the effect of the coking. The contrary has been shown to take place with the Virginia Midlothian coal.

By reference to the accompanying table of the experiment, and to that of deductions, it will be observed that the coke weighed at the rate of 31.57 pounds per cubic foot; while the average weight of the coal from which it was formed will hereafter appear to have been 54.287 pounds per cubic foot. Hence the loss by coking, of 17.281 per cent., will leave 44.907 pounds of coke from one cubic foot of raw coal. It follows, that the en-

largement of bulk has been 42.25 per.cent.

From the account hereafter to be presented, it will appear that the total waste, in ashes, clinker, and fine coke, from Neff's coal, was, on an average of four trials, 10.956 per cent.; while from the coke it was 13.515. The difference, 2.559, is 18.934 per cent. of the latter number, and indicates the ratio of loss in weight which the coal sustained in coking; but, as this is greater than 17.281, obtained by weighing the coke, we may infer that more unburnt matter passed through the grate while burning the coke, than had escaped while the coal was under trial. The difference is 12 per cent.

It appears that, during steady action, the draught gauge, when using coal, with air plate closed and damper drawn 8 inches, stood at an average height of 0.388 inch, burning 196.6 pounds of coal per hour, and evaporating 1,060 pounds of water per hour; and that when using coke with a like arrangement of damper and air plate, the gauge marking 0.361 inch, the weight of coke burned per hour was 118.5 pounds, and

the water evaporated was 932 pounds per hour. Hence we have 126.6: 118.5::0.388:0.363; proving that the amount of combustion was very nearly proportioned on the two occasions to the force of the draught; while 0.388:0.361::1,060:985, which proves that the evaporation was 53 pounds per hour less rapid with the coke than with the coal, even supposing the draught of the chimney to have been the same in both cases. The cause of more active draught during the day on which the coal was burned may probably have been the prevalence of a northwesterly wind, which generally, from the position of the building containing the apparatus, was observed to augment sensibly the force of the draught.

On comparing the evaporative power of the pound of coke with that of the same weight of Neff's coal, it will be observed that the latter was 9.742, and the former 8.997. As the waste from coal was, on the day of the first trial alluded to, 11.792 per cent., and 13.515 for the coke, the evaporative power in the unit of combustible matter in coal is 11.044, and in coke 10.381. Thus it appears that the combustible matter in the coke

is 5.8 per cent. less effective, pound for pound, than that in the coal.

The comparison of this coke with that from Midlothiau coal and with the natural coke will make it evident that the evaporative power of the combustible matter in each was almost exactly the same—being 10.381 for Neff's Cumberland coke, 10.343 for Midlothian coke, and 10.389 for natural coke. But while, as just seen, the coke of Cumberland coal is 5.8 less effective in its combustible constituents than the coal, in the Midlothian the reverse is true; the coke is 5.005 per cent. more efficient in the action of its combustible part than the original coal is in that of its compound of fixed and volatile combustibles. The time required by this coke

to bring the boiler to steady action was 1.166 hour.

In the preceding article it has been seen that the Midlothian coal lost of its weight in coking 19.14 per cent., and gained in bulk 18.37 per cent. And as it was found that, when submitted to rapid distillation in a close vessel, specimens of the coal from which it was produced lost about 30.2 per cent., it is evident that of this quantity there remained in the coke 11.06 parts. If the water proved to have been imbibed by the coke (2.81 per cent. of its weight) be added to the apparent diminution by coking, it will give 21.41 per cent. as the quantity of volatile matter expelled, leaving only 8.79 parts remaining in the coke when first raked from the heap. This is but little more than two-thirds as much as in the natural coke already described, which, by an average of seven trials, contained 12.86 per cent. of volatile matter. As above stated, the Cumberland coal lost of its weight 17.28 per cent., and gained in bulk no less than 42.25 per cent.

The above results, which were obtained by working on a practical scale, may be compared with those which are known to be realized in practice

by the different modes of coking adopted in the arts.

1. By coking in uncovered heaps of coarse lumps, (as at many of the iron works in Great Britain, France, and elsewhere,) and only covering up the ignited mass when flame ceases to be emitted. By this process, the loss in weight at Plymouth is stated to be 17, at Penn-y-darran 20, and at Dowlais 34 per cent.\* This last is, no doubt, far greater than is

<sup>\*</sup> See Mr. J. H. Alexander's Report on the Manufacture of Iron.

necessary, owing to the cheapness of coal, and the consequent neglect of economy in the management of the coking process. The coals at Dowlais and at Penn-y-derran bear a strong analogy to that of Cumberland, but have rather less volatile matter. Highly bituminous coals, coked in uncovered heaps, lose from 55 to 60 per cent. of their weight, and those of medium quality from 45 to 50, and those of still lower bituminousness from 30 to 40 per cent.\* In all these cases, a considerable loss occurs from burning away some portion of the solid carbon on the exterior of the heap, before the slack and cinders are placed upon the coke to extinguish the fire.

2. By coking in-stacks, (that is, in well-covered heaps of coal from 10 to 15 feet in diameter,) as followed in Staffordshire, coals of high bituminousness lose from 50 to 55, and those of a drier nature from 35 to 40

per cent.

3. By coking in close ovens, the coal of Rive-de-Gier yields 69 per cent. of coke, whereas by the first of the above methods it gives but 45 or 50. In the close oven, the gain of bulk is from 22 to 23 per cent. In the close oven, highly bituminous coals yield from 65 to 66 per cent.; but in the open heap only from 40 to 45, and this with an actual diminution of bulk.

4. By coking in gas retorts, the Deane coal of Cumberland (England) gains in bulk nearly 30 per cent., and loses in weight 25 per cent.; Cartisle coal nearly the same; while Cannel and Cardiff coals gain in bulk 30, and lose in weight 36.5 per cent. Bewick's Wallsend coal loses 30, and Russell's Wallsend 30.7 per cent. by the same process.

Other important particulars, in relation to this material, will be found ranged under the proper heads in the general synoptical table of deduc-

tions following this class of coals.

#### TABLE XLVIII.—DEDUCTIONS FROM TABLE XLVII.

# Experiments on coke of Neff's coal.

	Nature of the data furnished by the preceding table.	Trial.
		October 21
	Total duration of the experiment, in hours	25.133
	Duration of steady action, in hours	5.966
	Area of grate, in square feet	14.07
	Area of heated surface of boiler, in square feet	377.5
	Area of boiler exposed to direct radiation, in square feet	18.75
	Number of charges of coke supplied to grate	16.0
	Total weight of coke supplied to grate, in pounds	1010.25
	Pounds of coke actually consumed	994.25
	Pounds of coke withdrawn and separated after trial	16.0
	Mean weight, in pounds, of one cubic foot of coke	31.570
	Pounds of coke supplied per hour, during steady action	118.547
	Pounds of coke per square foot of grate surface, per hour	8.427
	Total waste, ashes and clinker, from 100' pounds of coke	13.518
	Pounds of clinker alone, from 100 pounds of coke	3.550
	Ratio of clinker to the total waste, per cent	26.623
	Total pounds of water supplied to the boiler	7866.0
	Mean temperature of water, in degrees Fahrenheit	620.0
	Pounds of water supplied at the end of experiment, to restore level -	417.0
	Deduction for temperature of water supplied at end of experiment, in pounds	
	Pounds of water evaporated per hour, during steady action	931.94
	Cubic feet of water per hour, during steady action	14.91
	Pounds of water per square foot of heated surface per hour, by one calculation	
	Pounds of water per square foot, by a mean of several observations -	2.47
	Water evaporated by 1 of coke, from initial temperature (a) final result	7.85
	Water evaporated by 1 of coke, from initial temp. (b) during steady action	1
	Pounds of fuel evaporating one cubic foot of water	7.95
	Mean temperature of air entering below ash pit, during steady pressure -	75°.0
	Mean temperature of wet bulb thermometer, during steady pressure	65°.0
	Mean temperature of air, on arriving at the grate	2190.57
	Mean temperature of gases, when arriving at the chimney -	276°.93
	Meafi temperature of steam in the boiler	2380.21
	Mean temperature of attached thermometer	70°.36
	Mean height of barometer, in inches	29.876
•	Mean number of volumes of air in manometer	5.124
`	Mean height of mercury in manometer	0.544
	Mean height of water in syphon draught gauge, in inches -	0.360
	Mean temperature of dew point, by calculation	
	Mean gain of temperature by the air, before reaching grate -	59°.64
	Mean difference between steam and escaping gases	1440.57
Ì	Water to 1 of coke, corrected for temperature of water in cistern -	47.91
	Water to 1 of coke, from 212°, corrected for temperature of water in cistern	7.853
	Pounds of water, from 212°, to 1 cubic foot of coke	8.996
į	Water, from 212°, to 1 pound of combustible matter of the fuel -	*284.03
!		10.381
İ	Mean pressure, in atmospheres, above a vacuum	1.425
1	Mean pressure, in pounds per square inch, above atmosphere	6.285
	Condition of the air plates at the furnace bridge	Closed.
-	Inches opening of damper	Upper 8.

<sup>\*</sup> It will be seen, by a comparison of this number with one of the results of Beaver Meadow anthracite No. 5, that, bulk for bulk, this artificial coke is very nearly half as efficient as the anthracite.

#### No. 12.

#### Mixture of Beaver Meadow anthracite and Midlothian bituminous coal.

The mixture here referred to was, in the first trial, composed of two charges, or 4 cubic feet, weighing 218 pounds of average Midlothian coal, and eight charges, or 16 cubic feet, of the same sample of Beaver Meadow anthracite from the navy yard, on which some experiments have already been detailed, weighing 870 pounds; making in all 1,088 pounds of mixture.

In the second trial, the two charges of Midlothian coal weighed 217.75 pounds; and the eight charges of Beaver Meadow anthracite 866 pounds; or the mixture was 1,083.75 pounds. The anthracite was in lumps of about 4 inches in diameter.

The use of this bituminous coal does not appear to have greatly accelerated the action of the anthracite; though, in both trials, a charge of the latter was laid upon the grate before the fire of wood was commenced. From the time when the wood was withdrawn to that when the boiler was in steady action in the first trial, the period elapsed was three hours and fifty minutes; and, in the second trial, it was two hours and thirty-five minutes. By a reference to the table of deductions, it appears that the weight of water, from 212°, to 1 of the mixed fuel burned, was 8.86; while, from table XXXIX, it appears that the same anthracite alone gave 9.079 pounds of steam to 1 of anthracite. The sample of "Midlothian average" coal gave 8.29, as will be seen on referring to column 16 of table CXCVIII, and to line 41 of averages, table CXXXVII, in subsequent parts of this report.

It will be remarked that all the trials on mixtures were made in the earlier periods of experimenting, when the chimney was but 41 feet high, and the draught was consequently much inferior to what it afterwards became by the addition of 22 feet. But they are still comparable with

each other.

# FROM TABLES XLIX, L.

minous, and four-fifths Beaver Meadow anthracite.

A verages.	Remarks.
-	The period of steady action in the first trial is, perhaps, rather less than that here indicated. A good deal of uncertainty necessarily exists as to the relation between the quantity of coal on the grate and the water evaporated, at any assumed period of the experiments; and, consequently, in regard to the deductions dependent on those elements of the calculation.

#### No. 13.

#### Mixture of Beaver Meadow anthracite and Cumberland bituminous coal.

This mixture was, for the first trial, made up of 221.75 pounds of Cumberland coal, taken from a quantity in use in the navy yard, and 886.5 pounds of Beaver Meadow anthracite, of the same sample which has been referred to in preceding experiments.

In the second trial, the Cumberland coal weighed 204.5, and the anthracite 867.75 pounds. The moisture in the Cumberland coal was found by

trial to be 2.12 per cent.

In each case a charge of anthracite was placed on the grate before kindling the fire with wood; the only advantage of which was, that a bed of warm anthracite was prepared, on which to commence firing with the mixed coal when the steam was up, and the wood had been withdrawn.

The mixture of these two coals appears, by a mean of the two trials, to have brought the boiler to steady action in two and a quarter hours, and therefore to have been greatly superior to the anthracite alone in this particular, as the latter took 5.08 hours for that purpose. By a reference to the table LIV of deductions, it will be seen that the steam from 212° to 1 of this mixed coal was, on an average, 9.18; while for this Beaver Meadow anthracite alone, it was 9.079. From this statement, it is evident that, by the mixture of coal of low bituminousness with the anthracite in question, a considerable increase of activity in the fire takes place, with

an augmentation of the total evaporative power.

When a coal of high bituminousness, like the Midlothian of Virginia, is mixed with anthracite, the coking of the former material agglutinates together not only its own masses, but also those of the anthracite, covering up the surfaces of the latter, and preventing the easy access of air. For this reason, the fire becomes sluggish in its action; but, with a freeburning bituminous coal, like that of Cumberland, the lumps scarcely cohere together in coking, and still less do they adhere firmly to the anthracite. And, as the bituminous part of the mixture comes quickly to a state of ignition, it aids considerably the heating up of the anthracite to the temperature at which its combustion can commence. for the more prompt and vigorous action of the mixture now under consideration, than of that previously presented. Each ingredient of the mixture appears by the experiments to retain its distinct evaporative power; the Beaver Meadow anthracite alone being rather more efficacious than its mixture with Midlothian, and rather less so than that with the Cumberland coal.

It appears that on the first day's trial the mean weight of a cubic foot of the mixture was 55.412 pounds; but on the second only 53.612 pounds. The anthracite separately weighed 55.406 on the first day, and 54.812 on the second. This difference would be fully accounted for by supposing that the anthracite used on the first day was from the Beaver Meadow mine No. 5, and that employed on the second from slope No. 3; since, from the tables at pages 45 and 61, it appears that those two varieties differ from each other by rather less than 2 pounds per cubic foot; the former weighing the most, and possessing the highest evaporative power. From the table LIV of deductions, relative to the mixture now under considera-

tion, it likewise appears that the first experiment afforded a result in evaporative power, as seen in lines 40, 41, and 43, superior to that of the second; and this superiority amounts to about 2 per cent.—an amount very nearly agreeing with the superiority of the anthracite of slope No. 5 over that from No. 3.

It is worthy-of notice, that on the second day's combustion the difference of temperature between the steam and the escaping gases was 9.5°

greater than on the first day.

As to the rapidity of evaporation, line 21 of the table shows that on the first trial 13.37 cubic feet of water were supplied to the boiler per hour, and on the second 13.56; while, with the anthracite alone, it is seen, by table XXXIX, that the rate of evaporation with the same size of grate and the same height of chimney was but 11.142 cubic feet per hour when using the first variety of anthracite, and 7.709 for the second. Hence the average gain of activity by the mixed fuel over the anthracite is 4.04 cubic feet per hour, or nearly 43 per cent. By table LI, it appears that the average rate of evaporation by the mixture of anthracite and Midlothian coal was 11.818 cubic feet, and that the gain on the anthracite alone was, consequently, 2.393 cubic feet, or 20.5 per cent.

#### Remarks on the foregoing table.

It appears that the anthracites proper weigh, on an average, 53.35 pounds per cubic foot; and, consequently, require 42 cubic feet of space to stow 1 ton. The natural coke of Virginia requires 48, and the artificial coke from Midlothian and from Cumberland coal an average of 69.7 cubic feet to accommodate the same weight. Under the head of "evaporation," it will be observed that the average effect of 1 pound of anthracite was to

convert into steam, from water at 212°, 9.565 pounds.

The last two columns of the above table are devoted to an exhibition of the reductive power of the several coals, when tested by the method of the celebrated French chemist, M. Berthier. The present occasion may afford a suitable opportunity to state the precautions which were observed in conducting the experiments on this subject. The coals in their raw state were reduced to an impalpable powder. A separate experiment was made, to ascertain the quantity of moisture which they contained; and then on another portion, also in the raw state, the trial with litharge was made. The powder, generally not exceeding 20 grains, was very intimately mixed with about forty times its weight of good English litharge, and placed in the bottom of a clean Hessian crucible, of such capacity that, when the mixture was covered with 500 or 600 grains of pure litharge, it was not more than half filled. The crucible thus charged was placed on a brick support in the centre of the small furnace L, (fig. 2, plate 11,) in which the fire had been previously lighted, and suitably covered, to prevent the danger from particles of combustible matter falling into it. The heat was gradually brought up to redness, at which it was maintained for some ten or fifteen minutes, or until the ebullition of the mass had nearly abated. The heat was then pretty rapidly augmented until all the litharge resting above the charge was in complete fusion; at which it remained a few minutes, to allow so much action on the silica of the crucible as to facilitate the subsequent detachment of the button of lead from the unreduced oxide, as well as from the crucible itself, and to obviate error from the intermixture and adhesion of litharge. Wherever there was reason to believe that an imperfect result had been obtained, a repetition of the experiment was resorted to. It is obvious that all comparisons of this method of determining heating powers with the practical one by evaporation, ought to be made after deducting the proportion of waste or incombustible matter from the total weight of coal submitted to trial in each case. If we compare the numbers in the column which marks the production of steam to 1 of combustible matter from 212° with those found in the last column of the table, we have the following order, which shows how far the method of Berthier coincides in its indications with the operations of the steam boiler:

			Steam to 1 of combustible.	Lead reduced to 1 of combustible.
ı.	Peach Mountain -	-	- 10.871	33,492

#### General characters.

In specific gravity, coals of the free-burning class fall a little below the anthracites, ranging from 1.28 to 1.44. Their mean weight per cubic foot is, however, only two-thirds of a pound less than that of the first class. As they contain but a small portion of matter to be vaporized, they soon come to the temperature of full ignition. The considerable increase of volume which they take in coking, favors the subsequent rapid and effective combustion of their fixed carbon. In some cases, especially when brought very gradually to ignition, their masses of coke scarcely cohere, and the original forms of their lumps are in a measure preserved.

#### No. 1.

Bituminous coal from the New York and Maryland Mining Company.

This sample was accompanied by a letter from Mr. Henry Morris, of which the following is a copy:

"Washington, December 30, 1842.

"Sir: I am requested by William Young, Esq., president of the New York and Maryland Mining Company, to forward to the navy yard at Washington four casks of coal, marked Nos. 1, 2, 3, and 4. I herewith send them. Nos. 1, 2, and 4, are intended to be tested by Professor Johnson in evaporating water, so as to determine their value for the steam vessels; No. 3 to be tried in the anchor and cable shops, to determine its value compared with other coals for smith's use generally.

"Very respectfully, your obedient servant,

"HENRY MORRIS.

" Captain Kennon,

"Commander of the yard, Washington."

This coal was of the kind commonly denominated "Cumberland coal," derived from the extensive coal trough lying a few miles to the northwest of the town of Cumberland, Allegany county, Maryland.

Its exterior characters are—a structure varying from slaty to columnar; its color a dull or shining deep black, according as the former or the latter

portions are regarded.

The surfaces of fresh fractures are sometimes striated. An efflorescent sulphate of iron, in very thin lines, is occasionally discernible. The main cleat, or parting, is at right angles to the surface of deposition, and extends frequently through the slaty as well as the columnar portions.

The columnar portions are much more friable, less dense, and more free from earthy matter, than the parts which exhibit a slaty structure, as will be more particularly demonstrated in regard to another sample of coal from

the same district.

The specific gravity of two specimens from this sample was found to be 1.438 and 1.424; the mean of which (1.431) gives the calculated weight per cubic foot in the mine 89.435 pounds.

Twenty experiments in measuring and weighing charges of two cubic feet each, gave a mean weight of 53.7 pounds per cubic foot. Hence the actual weight per cubic foot in the merchantable condition is 0.6004 as great as the calculated weight in the mine.

On consulting the columns under the head "weight of charges of coal," it will be seen that the variation in the weight of two cubic feet was according to size of lumps, from 95.75 to 118.25 pounds; the mean of which

is 107, or 53.5 pounds per cubic foot.

It will commonly be observed that the greater weights are given when a considerable portion of fine coal is mixed with the lumps. Such will in general be found as an effect of giving the "average" sizes to coal, instead of its being measured and weighed entirely in lumps. This will be more fully evinced hereafter.

The space required for the stowage of one gross ton of this coal will

be 41.71 cubic feet.

The moisture found in the first of the above specimens was but 0.803, and in the second 2.77 per cent. In an experiment on 28 pounds dried in the steam apparatus, the loss was 1.785 per cent.; which may therefore be safely assumed as the weight of water in 100 pounds of this coal, after some months' repose under cover, and in a moderately dry situation.

In addition to the moisture, the volatile matter at redness was found to be in the first specimen 12.902, and in the second 11.65; or the total vola-

tile matter of the former was 13.705, and of the latter 14.44.

By complete incineration, the first left of a light gray ashes 18.93, and the second 18,318. Hence the composition of the two specimens may be stated as follows:

			Specimen a.	Specimen $b$ .
Moisture	-	-	0.803	2.770
Volatile combustible matter	•	-	12,902	11.650
Earthy matter	-	-	18.930	18.318
Fixed carbon	-	-	67.365	67.262
		•		
			100.	100.

Ratio of volatile to fixed combustible = 1 to 5.222, and 1 to 5.773.

In burning 2127.75 pounds of this coal, there were obtained in al. 280.677 pounds of waste, of which 155.75 were askes intermixed with minute fragments of coke, and 124.927 were clinker; or the latter was 44.5 per cent. of the total waste; and the mean of the latter, compared with the weight of coal consumed, is 13.19 per cent. This result differs widely from that obtained from the two specimens above described; but, on reference to the two following tables, in which the experiments on combustion are detailed, it will be perceived that they present even greater discrepancies between themselves. From the first trial, it appears that the per centage of waste was 17.903, and from the second only 7.514. During the second trial, was burned the residue, after portions had been taken to the anchor and chain shops from the hogshead which had been designated by the letter above cited for trials on working iron.

From this it appears that the coal of this cask was much more free from earthy matter than that of the others. The specimens above analyzed

were taken from one of the other casks.

On reincinerating a portion of the ashes obtained from the two trials, they were found to have contained 13.27 of their weight of carbon. The cinder gave no reduction of weight by a like treatment. Hence it appears that the waste was really made up of—

Ashes	-	-	135.09 <b>5</b> p	ounds	= 6.349  pe	r cent. o	f the coal.
Clinker	•	•	124 927	66	5 870	66	46
_ Carbon	-	-	20.675	46	0.971	44	46

The clinker is in large spongy masses of a black or a deep brown color. Portions of unreduced shaly skeletons of the fragments of slate adhere to the exterior. This large amount of clinker would constitute a serious objection to the use of the coal under steam boilers. The purest portions burned on the second day's trial gave 3.4 pounds of clinker to 100 of coal.

The ashes weigh 37.79 pounds per cubic foot, and the clinker 41.75 pounds.

[ 386 ]

After two days' burning, the flues yielded of soot and dust 8½ pounds; of which 52.73 per cent. were volatile and combustible, and the rest a light red gritty ash—rather lighter in color than that from the reincincrated

ashes of the grate.

The trial of this coal in the chain shop proved it to work remarkably well, producing a strong heat without a great deal of flame. Sixty pounds of it were found sufficient for the putting in and finishing of 20 links of a linch chain—a higher result than was obtained from any other coal tested on the same chain. The cinder is small in quantity, and very little or no smoke was given off. The sample, having been selected expressly for this object, was doubtless more favorable in its effects than would have been the other portions of the sample, which, as above stated, yielded upwards of 17 per cent. of earthy residuum, instead of 7.5 per cent., as given by this cask. In the anchor shop, it was found to work very clear from einder, to give a very light coke, but not to be capable of forming a hollow fire at all.

The facility with which this coal ignites, and comes to a uniform rate of combustion, is indicated by the time occupied from the commencement of charging to the arrival of the period of steady action in the boiler. This on the first trial was 1.25 hour, and the second 1.416 hour. In the quantity of unburnt coke withdrawn after the fire had become extinct, (which was in the first case 15.25, and in the second but 5 pounds,) we have an index of the degrees of facility with which the combustion is continued.

In burning this coal, it was remarked that it ignites readily; burns with a deep red flame of moderate size; agglutinating while coking into tolerably solid masses, preventing the falling of fragments through the interstices of the grate. The coke is consumed more slowly than that of the highly bituminous coals. During the first trial, it was twice found necessary to remove a stratum of clinker from the grate, as the combustion became impeded. On the second trial, when the purer coal was used, this expedient was unnecessary—the fire continuing sufficiently active during the day.

Tried by litharge, specimen b (of which the specific gravity and the earthy impurity were less than in the case of a) gave but 24.775 times the weight of the coal in metallic lead. But, as there were 18.318 per cent. of earthy matter in this coal, the truly combustible portion was only 81.682 parts in 100; and dividing the above weight of lead by this, we obtain 30.331 as the number representing the reductive power of the combustible

matter.

# Maryland Mining Company's coal.

Averages.	Remarks.
10.125 53.7002 88.371 6.2805 12.7085 5.4259 43.454	The great difference in the amount of earthy matter, on the two trials, has already been referred to.
799.887 12.795 2.1195	
8.678 9.06 7.2201	The difference in the results of the two trials is explained by the difference in the amount of waste in the two cases, respectively.
250°.2 294°.25	
0.2315 157°.805 61°.921	
8.6487 9.7774	
9.7774 5 <b>24</b> .855 11.2078 1.445 6.5797	The difference of evaporative effect of the coal on the two trials in line 41, is made to assume an opposite character in this line, by the deduction in each case of the amount of waste.

No. 2.

Bituminous coal from Mr. John Neff's mines, in the neighborhood of Frostburg, above Cumberland.

This sample, sufficient for four trials on evaporation, was taken from a boat load of the same coal delivered by the proprietor, under a contract with the department, at the navy yard, Washington.

In exterior characters, this coal is generally similar to all those from the same district which have been examined. It was taken indiscriminately from the heap, and the lumps were not separated from the fine parts.

The larger masses exhibit the same crystaloid appearances already no-

ticed, with the occasional occurrence of a radio-striated surface.

The main partings are perpendicular to the surfaces of deposition. The partings of "clod," or carbonaceous matter, retaining something of the organic structure, are pretty abundant, and fractures are easily made, which display the forms of vegetable impressions.

The specific gravity of two specimens was found to be, respectively, 1.3429 and 1.3221, whence the mean weight per cubic foot in the mine is

83.28 pounds.

Forty-trials by measuring and weighing in the charge box showed the mean weight per cubic foot, in the marketable state of average fineness, 54.287 pounds; or the weight calculated from the specific gravity is to that obtained by experiment as 1 to 0.6519.

The space required for the stowage of 1 gross ton is 42.126 cubic feet.

The extremes of weight per cubic foot in the whole series are  $\frac{98.75}{2}$  = 49.375, and  $\frac{117}{2}$  = 58.5, as will be seen on consulting the column of charges in the tables of experiments. The mean of these two (53.927) is sufficiently near the general mean above given, to warrant a full reliance upon its realization in practice.

The trial for moisture in the steam-drying apparatus resulted in the ex-

pulsion of 11 ounces from 28 pounds of this coal, or 2.455 per cent.

The volatile matter of the first specimen, of which the specific gravity is given above, was found to be 14.05 per cent., and that of the second 16.21 per cent.

The incineration of the same specimens lest of the first 11.414, and of the second 8.538 per cent. The ashes are moderately dense, and of a

nearly flesh-red color.

There were burned in four trials 4315.38 pounds of this coal, and withdrawn from the furnace 196.25 pounds of clinker, equal to 4.5446 per cent.; and 277.008 pounds of ashes, equal to 6.4106 per cent. Hence the clinker

is 41.468 per cent. of the total waste.

The clinker is in dark brown, spongy, rather friable masses, including considerable portions of shaly and other unvitrified materials, which are of a somewhat lighter color than the portions which have undergone complete fusion. It does not adhere to the grate, or spread into impermeable sheets, like the cinders of some other coals which have been examined. It contains 0.896 per cent. of carbon. Its weight in the charge box was found to be 32.12 pounds per cubic foot.

The ashes are of a reddish gray color, and weigh 37.2 pounds per cubic

foot. They contain 10.06 per cent. of carbon.

The soot taken from the flues after four days' burning weighed 14.625 pounds, and was of such density that 12.64 pounds made 1 cubic foot. Its incombustible portion is 33.16 per cent.

The facility with which this coal ignites is indicated by the times required in the four trials to bring the boiler to a uniform rate of evapora-

tion. These were—

1.416 hour for the first; coal in lumps.
2.500 hours for the second; coal all fine.
1.800 hour for the third; coal mixed.
1.000 hour for the fourth; coal in lumps.

Mean

1.679

It is evident that the coarseness or fineness of the coal has been an important element in deciding the promptitude with which the combustion was brought to its average rate.

The mean weight of unburnt coke withdrawn at each trial was 6.155

pounds.

In the chain shop, 60 pounds of this coal were sufficient to make eight links of 115-inch chain. Its efficiency was, therefore, the same as that of Atkinson & Templeman's coal, to be hereafter described; and in the anchor shop it worked well, made a good hollow fire, but gave a large amount of cinder, which accords well with the considerable per centage of waste drawn from the steam boiler furnace.

A trial by the oxide of lead resulted in reducing of metallic lead 26.457 times the weight of raw coal employed. Deducting the ashes, 11.414 per cent., the lead to 1 of remaining material was 29.866; and deducting farther 2.455, the per cent. of moisture determined in the large way, the lead

to 1 of real combustible is 30.717.

In the gas works, this coal would be found to produce a gas too small in quantity, and too low in illuminating power, to be employed with profit.

In the blast furnace, it will sustain the same character as the other samples from the same coal region, with perhaps the exception of demanding more expenditure of power in reducing its higher proportion of earthy impurities.

It forms a dense coke, very suitable for smelting iron. An experiment of considerable magnitude on coking this coal was made for another purpose, while the experiments on evaporation were in progress. The evaporative power and other properties of that coke have already been detailed.

From preceding data, the composition of this sample may be stated as:

follows:

Moisture, from drying 25 pounds - - 2.455
Volatile matter other than moisture (two specimens) 12.675
Earthy matter, from 4318.38 pounds - 10.343
Fixed carbon, by difference - 74.527
Ratio of volatile to fixed combustible - 1:5.88

By reference to the column of "remarks" in the tables of experiments, it will be perceived that the combustion of this coal caused in the grate bars a constant tendency to redness, and a consequent liability to flexure and derangement.

Morning clear; wind SW., light; double weights on safety valves.  Commenced firing; water in boiler 0.1 inch below normal level.  Wood sonsumed, 93 lbs.; commenced charging with coel; steam escapes by removing second weight from valve at 7h. 26m.; damper set at 6 inches.  To prevent priming, the water in boiler to be kept 1 inch below true normal level.  Steam showed to escape from back valve at 8h. 35m. a. m.  Smoke 20" in reaching chimney top; syphon, 0.32; filled tank at 9h. 55m. a. m.  Fire in full action.  Filled tank at 2h. 50m. p. m.  Removed clinker from grate.  The first charge of coal contained one large lump, the ninth was all fine, the other eight about an average.  Very little smoke from chimney to-day.  Contents of ash pit thrown on grate at 5h. 15m. p. m.; damper set to 3 inches; water 1 inch above normal level. Water 0.8 inch below normal level; damper entirely closed.

#### No. 3.

### Bituminous coal sent by Captain William Easby.

This sample of coal was accompanied by the following letter:

"Washington, January 13, 1843.

"Six: I herewith send one hogshead, one tierce, and three barrels, of Cumberland coal, for the purpose of having its qualities tested. Will you be pleased to dispose of it as you think proper? The coal has been taken from a new mine called 'Coal-in-Store.' The casks are marked 'William Easby, Washington; coal from Coal-in-Store, near Cumberland, Maryland.'

"I am, sir, very respectfully, your most obedient servant,

"WM. EASBY.

#### "Captain B. Kennon."

In its exterior characters, this coal strongly resembles both the two samples from the same district, which have already been described. It is composed of alternating plies of a bright and a dull black color—the former belonging to the semi-crystalline or columnar portions, and the latter to the amorphous or slaty parts. The partings are perpendicular to the surfaces of deposition. These partings are frequently marked with small circular and other spots of sulphuret of iron. Fractures do not readily take the direction of the horizontal partings, so as to display the forms of organic bodies.

The specific gravity of two specimens was taken. The first gave 1.3046, and the second 1.3092; the mean of which indicates a weight in

the solid coal of 81.685 pounds per cubic foot.

Eleven trials in the charge box gave the mean weight per cubic foot 53.466 pounds, or 0.6545 of the calculated weight derived from the specific gravity. It proves that 41.896 cubic feet of space will be required for the stowage of 1 ton. The moisture, determined from the two specimens above referred to, was 0.804 for the first, and 1.07 for the second; or a mean of 0.937 per cent.; 28 pounds, dried in the steaming apparatus, lost only 3 ounces, or 0.6696 per cent.

The volatile matter, other than moisture, was in the first specimen

14.811, and in the second 15.158 per cent. of the weight of raw coal.

A higher proportion of earthy matter was found in the specimen which had the highest specific gravity—the first giving as the mean of the two trials, differing but little from each other in result, 4.056; and the second, by two identical results, gave 6.52. Hence, of these two specimens we have the composition as follows:

					Specimen a.	Specimen b.
Moisture	•	•	•	<b>~</b>	0.804	1.070
Other volatile	matter	-	•	-	14.811	15.158
Ashes -	•	•	•	•	4.056	6.520
Fixed carbon	•	•	,•••	•	80.389	77.252
					100.	100.
Fixed to volat	ile com	b <b>us</b> tibl	e as	-	5.423:1	5.096:1

The coke is in a well-formed mass; the parts completely agglutinated,

having a striated surface, silky lustre, and porous texture.

The combustion of 1,158 pounds of this sample left 97.09 pounds of waste, composed of 15.5 pounds of clinker, and 81.59 of ashes; or the whole was 8.3846 per cent. of the coal burned. The ashes lost by reincineration in the platinum capsule 12.87, and the clinker 1.143 per cent.; so that the actual quantity of incombustible matter left in the furnace was but 84.82 pounds, or 7.325 per cent. of the coal burned.

The ashes weigh 39.01 pounds per cubic foot, and the clinker 29 pounds. The latter is, in all respects, similar to that obtained from the preceding samples of coal, and bears to the total waste the relation of 15.9 per cent.

Of soot and dust, there were found in the flues 5.25 pounds, weighing at the rate of 16.68 pounds per cubic foot; and of which 47.39 per cent. was either volatile or combustible matter, and 52.61 ashes of a reddishgray color. This, added to the waste from the furnace; makes the total

waste from the coal 8.083 per cent.

The ashes of this sample (both those from the hand specimens analyzed, and those from the furnace) are almost identical in color and other sensible properties with those from the coal of Messrs. Atkinson & Templeman; the latter having only a slightly darker tint in the residue from the ashes, and a trifle lighter one from the clinker. They seem to indicate that both came from the same member of the coal series.

The time required by this coal to bring the boiler to steady action was 1.75 hour. The quantity of coke left on the grate was 18.25 pounds. Both these circumstances indicate greater difficulty in exciting and sustain-

ing combustion than had been experienced in the preceding sample.

A trial of heating power by the oxide of lead resulted in producing of metallic lead 30.155 parts for each part of coal employed. As the moisture and earthy matter together were 7.83 per cent. of the raw coal, the quantity of combustible matter by which the reduction was effected was 92.17 per cent. Hence the lead to 1 of combustible is 32.695.

For the purposes of smith work, domestic use, the production of illuminating gas, and the manufacture of iron, the same general remarks will apply as were made in reference to the sample last described, with the additional advantage to this sample of a greater freedom from earthy matter.

5	Mean pressure, in pounds per square inch, above atmosphere	6.949
8	Condition of the air plates at the surnace bridge	Open de close
7	Inches opening of damper	Upper 8.

<sup>\*</sup> In nearly all the Cumberland coals, it appears that the water to one of coal, by the calculation for a final result, is less than that during the assumed period of steady action. This arises, no doubt, from over estimating the weight left on the grate at the termination of that period. The large quantity of waste then filling the grate may have very naturally led to this result.

† By a preceding discussion, (see page 20, nets,) the velocity of the motion of air at ordinary

temperature, when the gauge is .333, should be about 12.08 feet per second.

\* The air plates were kept open for about half the period of this trist.

#### No. 4.

Biluminous free-burning coal from Alkinson & Templeman, of Cumberland, Mgryland.

In reply to an inquiry relative to the origin of this sample, the following information was received:

"Cumberland, Maryland, March 16, 1844.

"DEAR SIR: Your favor of the 13th instant, in regard to our coal, came-

to hand in due time, and we hasten to reply.

"The sample to which you allude was taken from a vein 9 feet some inches in thickness, on the eastern slope of Dan's mountain, about 40 feet below the surface of the earth, on a stream known by the name of Clary's run, two miles south of the national road. The vein is solid, and without slate, and now worked so as to be mined in lumps. The sample sent was taken direct from the mines, and must have been mined from two to three weeks before received by you.

"We are, dear sir, your obedient servants,

"ATKINSON & TEMPLEMAN.

# "Professor Walter R. Johnson, "Philadelphia."

The character of this coal is that of a mixed columnar and slaty mass; the former being possessed of a deep shining jet black color, a friable consistence, and occasionally a striated surface, with a semi-conical radiated arrangement of the striæ. The main partings are perpendicular to the surfaces of deposition; but the cross cleats, or partings, are oblique to both. Beautifully iridescent surfaces are occasionally met with. Thin plies of sulphuret of iron are visible in some specimens; and specks of the same in an efflorescent state, having developed the sulphate of iron, are apparent after some twelve or fourteen months' exposure to the air.

The specific gravity of two specimens was found to be, respectively, 1.322 and 1.305; from the mean of which the calculated weight of a cubic

foot is 82.09 pounds.

The mean weight of the same bulk of coal, as weighed in twenty-two charges of 2 cubic feet each, was found to be 52.92 pounds, or 0.6446 of the computed weight. Hence, the bulk required for the stowage of 1 tons is 42.328 cubic feet.

This coal appears to have very little tendency to absorb moisture. In the analysis of the first of the above-mentioned specimens, it gave but 0.53 per cent. of loss after heating to 300°; the other specimen weighed: exactly the same after drying as it did before.

A trial of 28 pounds in the steam apparatus over the boiler, for two days,

caused the expulsion of only 2 ounces of moisture, or 0.446 per cent.

The volatile matter, other than moisture, expelled in coking at a bright red heat, was found to be, in one specimen, coked with but moderate rapidity, 12.536 per cent.; in the other specimen, it was found, by a rapid application of heat, to be 17.411 per cent.

On incinerating the first specimen, the earthy matter was found to be 5.653, that of the second 5.239; the one possessing the highest specific gravity giving (as most commonly happens) the greater proportion of ashes.

14

From these data, it appears that the two specimens are composed as follows:

Of moisture -	•		٠.		, ,	Specimen a 0.530	Specimen b. 0.000
Of other volatile mat	ler	•	-	-		- 12.536	17.411
Of earthy matter -	•	•	-	-		- <i>5</i> .653	<b>5.23</b> 9
Of fixed carbon -	•	•	•	-		- 81.281	77.350
						100.	100.

Hence, the fixed carbon left, after slowly coking a, was 6.483 times as heavy as the volatile matter expelled; and, after rapidly coking b, it was but 4.442 times as heavy. Hence, the advantage of slow coking for economical purposes, as will be further developed hereafter.

In the two trials of this coal under the steam boiler, there were consumed 2,318.25 pounds. From this were derived 183.708 pounds of waste, made up of 133.958 of ashes,, and 49.75 of clinker. Hence the mean per centage of waste is 7.925; that of the ashes being 5.779, and that of the clinker 2.146.

Reincinerating the ashes caused them to lose 11.35 per cent. of their weight, and the clinker 0.485 per cent.; so that the former is reduced to 5.094, and the latter to 2.042 per cent. of the weight of coal; or the total earthy residuum thus derived from the furnace is 7.136 per cent.

There were obtained from the flues after two trials 11½ pounds of soot; of which 10.6 per cent. were found to be matter volatile at a red heat, being doubtless salts of ammonia; 49.5 combustible carbon, and 39.9 a light-colored ash, very similar to that derived from the reincineration of the ashes. Of the carbon, a considerable portion must have been derived from the wood used in heating up the apparatus during the experiments; of which 502½ pounds had been employed. The coal, therefore, gave for total waste 7.334 per cent. of absolutely incombustible matter.

A trial of this coal, by separating nearly equal small fragments from forty specimens of the sample, was made, in order to ascertain the practicability of deciding by this means the average constitution of the coal. The mixture of these fragments was completely pulverized.

When thoroughly dried, it lost	0.508	per cent.
When coked to bright cherry red heat, it lost in addition	15.532	"
When completely incincrated, it left of light pink-colored		
	10.372	66
And showed, of course, the amount of fixed carbon to be	73.588	4
• · · · · · · · · · · · · · · · · · · ·		
	100.	

From this, it appears that the fixed carbon is 4.738 times the weight of the volatile combustible.

The clinker is mostly in small fragments of a light brown passing into a yellow color. The tendency to vitrification is very moderate, and is confined to the darker colored partions. The rest appears to be adhering masses of slaty fragments, constituting the larger portion. It manifests no tendency to adhere to the grate bars. The ratio of clinker to the total

waste is but 20.8 per cent. The color of the pulverized and reincine-rated clinker is a light reddish brown; of the askes, a much lighten tint of red; and from the soot, askes of a still lighter-color were obtained. The clinker weighs but 31.62, the askes 38.92, and the sopt 15/77 poundamer cubic foot.

The time required for this coal to bring the boiler to a uniform rate of evaporation, was in the first trial 0.75, and in the second 1.216: hour, or a trifle less, on an average, than one hour from the time when the charging commenced.

The weight of coke left unburnt was in the first trial but 4.375, and in the second only 5.575 pounds; while that left in the clinker and ashes amounted, as above shown, to only 0.789 of one per cent. All these facts indicate great facility in commencing and continuing the ignition.

The trials of this coal in both the smith shops gave great satisfaction. Sixty pounds of it in the chain shop were found sufficient to make eight links of a chain cable formed of iron 115 inch in diameter; and the same weight again tried on a chain 18 inch in diameter was found sufficient to make eighteen links. It makes a dense and hot fire, with moderate flame.

In the ancher shop, it was found to make a hollow fire of moderate size, strong, and durable. The only circumstance detracting at all from its value was, that the cinder was rather too bulky, tending somewhat to obstruct the tuyeres.

As a fuel for domestic purposes, it possesses on the one hand a flame abundantly sufficient to give cheerfulness to the aspect of a parlor five, and, on the other, a durability approximating that of some of the lighter anthracites. The proportion of gas is too small to render it available for illuminating purposes—especially where it comes in competition with coals of the highly bituminous class, as those of Pittsbarg, of Richmond, of Nova Scotia, or of Great Britain.

As a furnace coal, for the manufacture of iron, it will be found among the best of the bituminous class, since, either with or without previous coking, it may be very advantageously employed in the blast furnace. It is very similar in constitution to the furnace coals of Merthyr and Llanelly, in Wales, with the exception of possessing a greater proportion of earthy matter.

A single trial for heating power by the oxide of lead of specimen b, above referred to, (having the lowest specific gravity, and the least of earthy matter, resulted in giving 28.49 times its weight of metallic lead. Deducting the weight of earthy matter, this would be 30.06 parts of lead to one of combustible.

The sample of coat in a box accompanying this, and consisting of less than 200 pounds, stated to be from the "Forks of Jennings's run," which are 6% miles above Cumberland, was too small in quantity for a trial inder the steam boiler.

Its character is that of a friable coal of columnar structure, falling mostly into slack, having a shining jet black color, and being much more free from slaty matter than most of the samples of coal from the Cumberland district which have fallen under my observation. It seems to have been carefully selected, or at least much more skilfully mined than generally happens in that region.

Sixty pounds of it in the chain shop were found adequate to the making

-effeight links of a chain 144 inch in diameter. It was, consequently, equal in strength to the other samples sent by the same proprietors.

In the anchor shop it was found very favorable for the performance of small work, very pure, making a strong heat, but altogether unsuited for

forming a hollow fire.

ion, was found to take fire promptly when laid on a rather dull anthracite fire; burning with little or no smoke, and with a flame of moderate length. As the amount of vaporizable matter is far less than in many highly bituminous coals, it exhibits a prompt ignition, and none of that smouldering apathy which the latter generally display when first heated upon the grate.

The specific gravity of Jennings's run coal is 1.3092, which is identical with that of one specimen from the large sample. Its volatile matter was 1.7 per cent.; also nearly approximating the weight of the same material

found in that specimen.

Its earthy matter was 5.53 per cent., or a very little above the mean of the two specimens above referred to. Hence the ratio of the volatile matter to the fixed carbon is one to 4.556. The calculated weight of a cubic foot is 81.83 pounds.

The coal is very friable, being composed almost wholly of columnar plies, separated by thin films of pyritous matter, which easily effloresces, developing white lines of sulphate of iron. A specimen, which has been fourteen months in my possession, is already disintegrating from this cause, and fall-

ing into powder.

I have referred above to the relation of the sample of coal now under consideration to some of those found at certain celebrated localities in Wales. The same relationship may, in general, be traced between all the samples of free-burning coals both of Maryland and Pennsylvania, and those of some one or other of the great mining and iron manufacturing districts of that country. To facilitate comparisons, I offer the following condensed view of the results of very numerous experiments on the proximate composition of coals used at some of the most celebrated of those establishments. The experiments are those of Mr. David Mushet, and are contained in his valuable work on iron and steel. The coals referred to one locality were mostly from different beds, or from different plies of the same bed. They are generally used at forges, rolling mills, and blast furnaces, for the manufacture of iron.

The series in the table commences with such as are rather more bituminous than any of the free-burning class described in this report, and proceeds with those of less and less bituminousness, until it reaches the true anthracites, containing about the same amount of volatile matter as that of

Lyken's valley, heretofore described.

The table shows in part the remarkable variety of materials found in the great Welsh coal field, and the resemblance which it bears to the southern anthracite field of Pennsylvania, which, as elsewhere stated, is now known to afford bituminous coal at one extremity, and pure anthracite at the

#### · Taktelen vient of the proximate composition of Welsh furnace coals.

General exterior and other characters of the coals.

giance cost.

j

(7.) Structure either mixed of ready and granular, or wholly granular, very bright and chining; concentric circles sometimes are apparent at the fractures.

(8.) Forms generally rhomboidal; structure granular; mineralized charcoal intermixed with reedy laminus; cross partings more or less irregular.

(9.) Structure variable; reedy and granular intermixed; sometimes crystalloid, specular, glance, or anthracitous.

(10.) Either bright, reedy, in regular lamina, or intersected at right angles by partings producing brittleness; color cometimes dull black, having no proper cleavage, at others, the aspect is that of beautiful glance, having minute shiring lamina oblique to the surfaces of deposition.

(11.) Structure cometimes compact, minutely laminated. Some varieties have a reedings oblique

to the bed, some are graphitic in appearance, and others partly bituminous and partly anthracitous.

(12.) Several of these varieties are entirely anthracitous in character, and undergo no change of

form in coking; others have the usual characteristic of dry bituminous coals-

(13.) All these varieties are true anthracites; structure slaty; color brilliant black.

(14.) Some of these are decidedly anthracitous, others contain bituminous cement between the plies, and others still are entirely bituminous. This is, indeed, a transition coal.

(15.) Regularly crystallized, granular, or shining, without regular cleavages; surfaces sometimes plumbaginous.

(16.) Bright, chining, pitchy; grows more brilliant by pulverizing.

(17.) All these are true anthracites, with the ordinary characters pertaining to that class.

•	
10. <b>69</b> 91 5 <b>66.2</b> 5	The two trials of this coal give a remarkable coincidence of results, as well as a very high average amount of evaporation. It is, indeed, the highest result obtained dur-
11.6241	ing the research.
1.4612 / 6.8112	
-	The burning with open air plate seems to have produced but little effect on the effici.
	ciency of this coal.

No. 5.

Bituminous coal from the mines of Easter & Smith, above Cumberland, delivered for use at the navy yard, Washington; selected from a boat load, by Captain Easty.

This sample of coal was stated to be from the mines called "Coal-in-Store," the same from which a preceding sample sent by Captain Easby was also taken.

In its exterior characters, this sample strongly resembles that coal. In some cases, however, it exhibits larger portions of carbonaceous matter on the surfaces of deposition. A radio striated appearance occasionally occurs, and the alternating plies of columnar or crystalloid, and slaty or amorphous coal, are preserved, and often strongly marked.

The main partings are perpendicular to the surfaces of deposition; and cross partings at different angles to the same surfaces, giving the impres-

sion of a forcible bending of the plies, are not uncommon.

The specific gravity of one specimen which was analyzed, was found to be 1.4023, and of another 1.3628; the mean of which gives the calculated

weight of one cubic foot of this coal, 86.41 pounds.

Forty-eight trials in the charge box gave the weight of one cubic foot 53.174 pounds; being 0.6153 of the calculated weight from specific gravity. The space required for stowing one gross ton will be 42.126 cubic feet. The minimum weight of a cubic foot was 48, and the maximum 55.5 pounds, as will be seen by reference to the columns of weights of charges in the following tables.

The hygrometric moisture in this coal, as ascertained by an experiment in the large way in the steaming apparatus, was 0.893 per cent.; and the total volatile matter derived from the two specimens above given was, for

a 16.13, and for b 16.70.

The specimens a gave of earthy residuum 9.109, and 5.7.398 per cent. Hence the two specimens may be considered to have the following proximate constituents, viz:

•			Specimen a.	Specimen b.
Of moisture -	•	•	0.893	0.893
Other volatile matter	•	-	15.237	15.807
Earthy matter -	•	•	9.109	7.398
Fixed carbon -	•	•	74.761	75.902
			100.	100.

The volatile is here to the fixed combustible as 1 to 4.906 in the first, and

1 to 4.802 in the second specimen; and the mean is 1 to 4.854.

In the five trials of this sample under the steam boiler, there were burned

4,474.5 pounds; and the total waste withdrawn, exclusive of the ashes from wood used in heating up the boiler, was 435.75 pounds, equal to 9.739 per cent. Of this amount, 142.75 pounds, or 3.19 per cent., was clinker, and 293.04 pounds, or 6.549 per cent., ashes. Hence it appears that the clinker constitutes 32.756 per cent. of the total waste.

The ashes derived from the analyses of this coal are moderately light,

and of a nearly flesh-red color.

The clinker from the furnace is much like that from Atkinson & Templeman's coal.

The same light-brown color, imperfect vitrification, and adhering white shaly masses, are here equally conspicuous as in the case just cited. The

clinker weight 36.68, 13d the ashes 33.57 pounds per cubic foot. The ashes lost by reincineration 8.419, and the clinker 2.3 per cent. of weight. House the total abactus wester independent of the agot, is 3.1148 per cent.

After four days' burning, there were withdrawn from the flues 12.25 pounds of soot; and subsequently, after a single day's operation, 3.5 pounds more were collected. This material weighed at the rate of 24.28 pounds per cubic foot. It appears to have produced but little effect, as the evaporation was conducted with nearly as much economy on the fourth as on the first day's experiment. The seot contained 51.41 per cent. of earthy matter.

The time required to bring the boiler to a uniform rate of action in the

Fifth	•	-	-	•	-	•	•	1.400	<b>66</b>
•	Mean	-	• .	-	•	-	•	1.523	"

The quantity of coal withdrawn from the grate, and separated, was on an

average only 5.35 pounds.

The action of this sample, in all its applications, will be similar to that of the Cumberland coals above described. Deficient in volatile products for the purposes of making illuminating gas; well adapted to parlor grates, to smiths' forges where a hollow fire is not required, and to the manufacture of iron in the blast furnace, either with or without the process of coking, its high heating power will commend it for all these latter purposes; and if carefully mined, and kept free from slate and other impurities, it may sustain the character which this well-selected specimen has been enabled to establish.

A trial of heating power by the oxide of lead on 20 grains of specimen a, above referred to, resulted in reducing 600.2 grains of metallic lead, or 30.01 times the weight of raw coal employed. As that specimen contained 9.109 per cent. of earthy matter, the heating power of the combustible is

expressed by  $\frac{30.01}{9000} = 33.01$ .

I have mentioned the different characters which the several columnar and amorphous plies of this coal present. In order to illustrate the respective properties of the two, I employed a specimen in which the plies of columnar coal were of rather unusual thickness, and very brilliant in the surfaces of parting. From this specimen, a portion of the columnar or crystalloid part gave of volatile matter 18.28 per cent.; earthy matter of a reddish-yellow or fawn color 1.754 per. cent.; and of fixed carbon 79.966.

The volatile is, therefore, to the fixed combustible as 1 to 4.374. The coke produced by this portion was a bright intumescent porous mass.

The powder of this crystalloid coal was of a deep-brown color.

The amorphous or slaty ply of the specimen gave of a greenish-white ashes 14.736 per cent., and of volatile matter 15.976. Hence the fixed carbon is 69.288; and the volatile to the fixed combustible as 1 to 4.337.

The powder of this portion of the coal was nearly as black as the solid mass, the coke far less intumescent, and its particles less agglutinated, than those of the purer part of the lump. Twenty grains of the amorphous portion produced, when treated with oxide of lead, 25.764 times its weight of metallic lead; which, after deducting ashes, gives 30.216 times its weight of lead to 1 of combustible.

No. 6.

Bituminous coal from Cumberland, procured for use in the navy yard.

This is the same sample of Cumberland coal from which were taken the four charges used in making mixtures with Beaver Meadow anthracite, as

already detailed.

The only separate experiment made with this coal was in one of the preliminary trials of the apparatus. In that trial, the coal was used in heating up the boiler, as well as in generating steam. No decisive result could be, with confidence, deduced from that trial; and I therefore abstain from any other than a general exhibition (in the synoptical table which follows this class of coals) of such points as were determined by analysis, and such as an examination of the residua of the combustion enables me to offer. It will not fail to be observed, that the total waste from this sample was more than that from any of the samples sent for trial from the Cumberland region. The five samples thus sent gave an average of 9.939 per cent. of waste, including clinker and ashes; while the coal furnished to the yard gave 14.526 per cent. A similar, or greater, difference will be hereafter observed between the impurity of a sample of Midlothian coal purchased for use in the yard, and all the samples of the same coal sent by the company for these trials. This observation points to the necessity of greater vigilance in mining, and more caution in purchasing coal.

#### No. 7.

Bituminous coal from the Dauphin and Susquehanna Coal Company of Pennsylvania, sent by Isaac Lea, Esq., of Philadelphia.

The following statement, relative to the origin of this sample, is contained in a letter received by the undersigned, and dated

#### "PHILADELPHIA, August 18, 1842.

"DEAR SIR: I have just heard of the shipment from Dauphin of three hogsheads and one barrel of the Dauphin or Stony Creek coal.' It goes to the care of Mr. N. Hickman, Baltimore, with directions to forward it to Commodore Kennon, as you requested.

"I ordered it to be taken out of 'Perseverance vein,' wishing to send you fresh coal; but have some fears that it may not have been as well mined, or as well selected, as it ought to have been, as there was no regu-

lar miner on the spot.

"I beg that you will make all allowance for any defect that may arise from the circumstances—preferring to have no report rather than one which might deteriorate from the character already established.

"You have my best wishes for a satisfactory termination of your present

arduous duty.

"Very respectfully,

"ISAAC LEA.

In a verbal statement afterwards made, Mr. Lea mentioned that his fears above referred to, in regard to the selection of the sample, were subsequently ascertained to be in a measure justified; and that a part of it, instead of being freshly mined, had in fact been taken from a heap which

had been for two or three years lying near the mouth of the pit.

The exterior aspect of this coal is more anthracitious than bituminous. Fractures frequently follow the surfaces of deposition; striated and very smooth faces oblique to those surfaces not unfrequently occur. A set of shining faces, forming the main partings, appear to observe the general inclination of 80° and 100° to the surfaces of deposition. Alternating plies of bright and dull black present themselves conspicuously in the directions of the cross-partings, but they are less strongly marked than in the Cumberland coals.

The specific gravity of one specimen of this sample was found to be 1.6209, and of another 1.4431. The mean of these gives the calculated weight per cubic foot 97.5 pounds; whereas twenty-six trials in the charge box gave a mean of 50.538, varying from 46 to 55 pounds as the extremes, or 0.5184 of the calculated weight. The space required to stow one ton is 44.323 cubic feet.

The analysis of the two specimens of this coal, of which the specific gravity has been given, showed the first to contain 0.582, and the second 0.646 per cent. of moisture.

In the steam drying apparatus, 28 pounds lost in three days only 2

ounces, or 0.4464 per cent.

The volatile ingredients, other than water, in the first specimen were 14.148, and in the second 12.776. The coking gives a considerable increase of bulk, and the coke is tough and coherent. The gas burns with a bright yellow flame.

On two other specimens of this sample, four experiments were made by Dr. King, which afforded a mean of 14.562 per cent. of volatile matter; and the mean of the six, including the two on my own specimens, is 14.292. Besides these trials, made expressly to determine the proportion of volatile matter, and performed in close vessels, a set of four trials was made while performing the incineration of the first specimen, of which the result was 14.67 per cent.

The four experiments just referred to proved the earthy matter of the first specimen to be 17.94; and eight others, on the second specimen, gave 21.09 per cent. of the same materials. The ashes are bulky, slightly gritty,

and of a bright fawn color.

The presence of a considerable portion of oxide of iron is indicated by the color of these ashes, and becomes further apparent during the combus-

tion on the grate.

In three trials under the boiler, there were consumed of this coal 2,557.5 pounds, leaving of clinker 91.5, and of ashes 323.65 pounds: whence it appears that the former was 3.578, and the latter 12.658 per cent. of the coal burned; or the total waste drawn from the furnace was 16.236 per cent.

By reincinerating, the ashes lost 37.76 per cent. of their weight, and the clinker 1.69 per cent.; so that the amount of waste from the furnace was 11.396 per cent., and from the flues an addition (as seen below) of 0.098—making the whole 11.494 per cent. of matter actually incombustible.

[ 366 ] 236

The propertion of sulphur in specimen a, ascertained in the manner already described, was 0.269 per cent. Hence, admitting the volatile matter to have been correctly ascertained by the above experiments, we obtain for the composition of the Dauphin coal—

		100.	
Carbon, not volatilizable by heat alone -	-	74.214	. "
Earthy matter, from the furnace operations -	•	11.494	. "
Volatile matter, other than above (by six trials)	-	13.577	"
Sulphur, by trial on one specimen	•	0.269	"
Water, as proved in the large apparatus -	-	0.446	per cent

The clinker weighs 32.25 pounds per cubic foot; is chiefly of a reddishbrown color, with some yellowish-white portions; is porous, and often has large adhering fragments of slaty matter, but little vitrified.

The asires weigh 44.62 pounds per cubic foot, have a slight tinge of redness, and, when reduced to powder, become almost perfectly black, from the

unburnt coal which they contain.

After three days' burning, the flues afforded 5\frac{3}{2} pounds of soot and dust, weighing at the rate of 12.45 pounds per cubic foot; which obviously had but little effect in impeding the passage of heat into the boiler, since the efficiency of the pound of fuel was higher on the second day than it had been on the first; and the gas entered the chimney at a lower temperature on the third day than on either of the preceding.

This coal takes fire promptly. The time clapsed between the commencement of charging with coal, and the establishment of the rate of steady action, was on the first trial 0.75 hour, on the second 0.66, and on the third 1.08; or, on an average, about 0.83 hour, or 50 minutes. The average weight of unburnt coke left on the grate after each trial was 23.67 pounds.

In the smith's fire, the coal worked moderately well, but presented the objectionable feature of giving a large amount of cinder. Sixty pounds were found sufficient to make nine links of a chain 1 inch in diameter.

The sample was too small to afford an opportunity of making all the trials which might have been desirable. No trial is recorded as having been made in the office grate; but, from the characters it exhibited in the furnace, no reasonable doubt can be entertained of its proving satisfactory for domestic purposes.

A single trial of heating power by the oxide of lead on specimen a yielded 25.325 times its weight of metallic lead. Deducting 18.525 per cent., the sum of its earthy matter and moisture, this gives to 1 of combus-

tible a reductive power of 31.083.

The following tables exhibit the mode of action of this coal under the boiler; and the subsequent table of deductions exhibits all the important

conclusions to which they lead.

This sample of coal is interesting, as illustrating the passage of the anthracite beds of Pennsylvania, near their southwestern termination, into those of a decidedly bituminous character. In undergoing the process of coking, the masses became slightly agglutinated together, still retaining, to some degree, the original forms. The coke is tough, and has a brilliant plumbaginous lastre.

Note.—Under date of May 22, 1844, Mr. Lea gave the following information:

"DEAR SIR: I hear to-day, from the person who procured the coal sent to you from Perseverance vein, in the Dauphin Coal Company's lands, that there was not a single pound of it mined for the purpose of sending to you, agreeably to my orders; but that the whole of it was raked out of a heap of rubbish which had been lying at the mouth of the drift for three years, exposed to the ice of winter and heat of summer; and, of course, deteriorated. I expressly ordered it be mined fresh for the trial; but I am told to-day that there was not a pick put into the vein for the purpose."

"I am, very respectfully, your obedient servant,

"ISAAC LEA.

"Professor W. R. Johnson."

#### No. 8.

Bituminous coal from Blossburg, Tioga county, Pa., sent by the Arbon Coal Company.

The following letter contains the information required by the department to accompany each sample of coal furnished for trial in these experiments:

"BLOSSBURG, June 24, 1842.

" To the Board of Commissioners of the Navy Department:

"Gentlemen: In accordance with an advertisement published by the department in the Commercial Advertiser, New York, of April 14, 1842. calling upon proprietors of mines, and others furnishing fuel, to forward a quantity of the fuel they respectively furnish to Washington, for trial, the Arbon Coal Company have despatched to the navy yard at Washington two tons of the coal worked at their mines, for the above specified objects. This coal was worked in the month of January, at the mines belonging to the company, and situated in Blossburg, Tioga county, Pennsylvania, and has been lying exposed to the weather till packed for exportation, May 12, 1842. It forms a fair sample of the quality of the coal constituting the vein they now work. It is, on an average, three feet in thickness, pure, and of very superior quality. It is mined and filled into the railroad cars directly at the openings, is sent to Corning, and there tipped into the canal boats, which proceed through the Chemung canal to the New York and Erie, and so on to Albany and New York, where it would be most convenient to deliver any quantities that may be contracted for.

"I take pleasure in signing myself your very obedient servant, "J. W. JOHNSTON,

"Superintendent of Arbon Coul Company."

The exterior characters of this coal are a columnar structure, with the main partings inclined to the surfaces of deposition, in angles varying from 80 to 85 degrees. The color is a deep shining black, with but few plies of The horizontal partings are in some instances marked with efflorescent sulphate of iron, the presence of which is easily recognised by the senses. This efflorescence of the sulphuret into the sulphate appears to be the chief cause of the disintegration, more or less rapid, of the different coals in which it takes place.

The specific gravity of one specimen examined was found to be 1.3236, and that of another 1.9542. The latter doubtless contained an undue proportion of sulphuret of iron. Admitting the first to be a fair average result, the weight of a cubic foot will be 82.73 pounds. The weight in its merchantable state, as determined by 41 trials in the charge box, was from 49.625 to 57.25 pounds, and on an average 53.048 pounds per cubic foot. It follows that the space required for stowing one ton will be 42.221 cubic feet.

The moisture expelled from specimen a was 0.758, and that from b

0.683 per cent.

From 28 pounds dried in the steaming apparatus, 6 ounces of moisture were expelled, or 1.339 per cent.

In addition to the moisture, a heat of bright ignition expelled from spe-

cimen a 12214 per cent. of volatile matter, and from b 17.777.

Two other specimens afforded to Dr. King a mean of 16.26 per cent. of volatile matter; and the mean of all the trials gives the total volatile matter of this coal 16.119 per cent.

The sulphur in specimen a was found to be 0.853 per cent.

Four trials on the incineration of each specimen gave for a 5.40, and for b 13.246 per cent. of ashes. Before the incineration was complete, the last specimen, when withdrawn from the muffle, was found to emit a very strong odor of sulphurous acid. The ashes produced at the lowest temperature were of a purplish-gray color; those which had been more strongly heated, were of a deeper red, and had small masses of oxide of iron scattered through them. The ashes of specimen b were of an entirely different character—being grayish white, and more dense than those of the other.

In burning 4,295 pounds of this coal, there were produced of ashes 290.46, and of clinker 189.75 pounds; or the former was 6.763, and the latter 4.418 per cent. of the coal burned—the total waste being 11.181 per

cent.

The clinker is of a dark-brown color, having fragments of slaty residut intermixed, not remarkably porous, and considerably agglutinated. It weighs 30.87 pounds per cubic foot. The ashes weigh 44.5 pounds. The reinchmeration of ashes and clinker proved that the former had embraced 8.354 per cent., and the latter 0.436 per cent. of combustible; whence the absolute quantity of incombustible ingredients is 10.597 per cent.

The composition of the coal may be thus stated:

Moisture -	-	-	•	•	1.339	per cent.
Sulphur -	-	•	•	-	0.853	•
Other volatile matt	er -	-	•	•	13.927	66
Earthy matter	•	•	•	•	10.773	66
Fixed carbon	<b>.</b>	•	-	•	73.108	"
	•			-		
•	•				100.	

After four days' operations in burning this coal, there were obtained of soot 14 pounds, weighing at the rate of 12.06 pounds per cubic foot. This, when incinerated, gave 7.583 pounds of ashes, or 0.176 per cent. of the coal which is included in the earthy matter above given.

For the purposes of working iron, this coal will be found well adapted where a large hollow fire is not required. Sixty pounds of it were found sufficient to make 10 links of a chain 1% inch in diameter. For domestic purposes it will be equally appropriate, where a lively fire of medium-sized flame is desired, and where a high intensity of combustion is not necessary. If used in close stoves, or house-heating furnaces, the amount and character of its residuum will probably be found to interfere with a satisfactory application.

This coal takes fire promptly; 50.5 minutes was the mean time required by it to bring the boiler to regular action, after the commencement of charging. It also burns up tolerably clean; having, as will be seen from the table of deductions, left on an average only 13.75 pounds of unburnt coke

after each trial.

An experiment by the oxide of lead on specimen a, above analyzed, resulted in reducing 30.785 times the weight of coal employed. Deducting the earthly constituents, this gives 32.542 of lead to one of combustible matter of the coal.

No. 9.

#### Coal from Archibald McIntyre's mines, near Ralston, Lycoming county, Pennsylvania.

This coal was accompanied by no certificate or description stating its locality, or the time of mining it. The markings of the casks were relied upon for indicating its origin.

In external characters it strongly resembles the coal of Blossburg, and

perhaps even more nearly that of Quin's run.

It is deep black and brilliant in both the main and cross partings. The main partings are generally inclined to the surfaces of deposition in angles of 85° and 95°. Very brilliant and alternately rather dull lines of black mark the edges of the strata. It breaks into columnar masses, exposing little or nothing which could indicate the nature or amount of its impurities.

It came to hand mostly in the state of small lumps, or fine; was noticed as having the brighter portions in a crystalloid form, and being of a friable

texture.

Its specific gravity, as determined from two specimens, was 1.3949 and 1.3807, from which the calculated weight per cubic foot is 86.74 pounds; while 29 trials in the charge box gave the actual weight 55.379 pounds per cubic foot—equal to 0.6384 of the calculated weight; the least being 52.5, and the greatest weight 57.25 pounds. This proves the bulk of a ton to be 40.449 cubic feet.

The moisture in specimen a, above referred to, was 0.54, and that in b

0.601 per cent.

The trial of 28 pounds proved the moisture to be 0.67 per cent.

The sulphur in specimen b was found to be 0.0303 per cent.

The total volatile matter, other than water, was in specimen a 15.149, and in b 15.137. Five trials on two other specimens by Dr. King resulted in giving a mean of 13.3 as the total amount of volatile matter.

The mean of the two sets, or 14.507, is probably a fair representative of

this ingredient of the coal.

The two specimens were tried each four times, for the amount of earthy residua: a gave a mean of 11.96, and b of 8.7 per cent. The ashes from these analyses are almost perfectly white.

During the three trials of its evaporative power, there were consumed of this sample 3,073.25 pounds; and of waste, in the form of ashes, there were left 420.882 pounds, and of clinker exactly 100 pounds. The former

are 13.69, and the latter 3.25 per cent. of the coal.

The clinker weighs 34.37 pounds per cubic foot, and is variously colored, having undergone but little fusion, except on the surfaces of some of the silicious portions. The shaly portions retain nearly their original form, and appear to have merely parted with their carbonaceous matter.

The ashes from the furnace weigh 37.79 pounds per cubic foot, and present a gray color, showing numerous minute fragments of coal inter-

mixed.

The soot, of which 11.5 pounds were collected after three days' burning, weighed 16 29 pounds per cubic foot.

The clinker did not adhere to the grate, or cause any remarkable ob-

struction to the combustion, other than what might be expected from its considerable bulk.

Reincineration reduced the ashes 20.95, the clinker 9.93, and the soot 45.56 per cent. of their respective weights.

The composition of this coal may, therefore, be stated as follows:

Moisture, from drying 28 pounds	. •	<b>-</b> ,	•	- 0.670
Sulphur, from 1 specimen -	-	•	•	- 0.030
Other volatile matter, from 4 specimens	<b>-</b> 1 .	•	•	- 13.807
Earthy matter, from 3,073.25 pounds	-	•	•	- 13.961
Fixed carbon, by difference -	•	•	•	- 74.532
;			.	
·			: ;	100.

Volatile to fixed combustible 1:5.181.

The ignition of this coal appears to be effected with rather more difficulty than that of some others of the free burning class. It took 1.722 hour to bring the boiler to a steady rate of evaporation; and there were lest, on an average, 46.25 pounds of unburnt coke at the end of each experiment.

In burning, it produced a tolerably dense reddish flame; caked considerably; sent off a moderate quantity of smoke; but only caused a visible current at the chimney top during the application of fresh coal to the grate, and for one or two minutes following.

The heating power of this coal was tried by the oxide of lead on specimen b, above analyzed.

Twenty grains reduced 596.64 of metallic lead, or 29.832 times the weight of coal; which, after deducting 9.301, the amount of ashes and moisture in 100 parts of that specimen, gives the reductive power of the combustible matter of this coal 32.891, which is about the same as that of several anthracites tried by the same means. When tried in the smith shop for chain cables, this coal yielded results far from satisfactory.

The cinder was very abundant, and difficult of fusion; the coke hard and unmanageable after the flame had ceased. In the anchor shop it was found equally objectionable by the workmen who tried it. The fire, it was said, could not be kept hollow, notwithstanding the hardness of the coke, and the large quantity of incombustible matter impeded the blast.

Not being a full sample, there was not a sufficient quantity left of this coal to make any trials in grates for domestic purposes. This is the less to be regretted, since its heating power was fully ascertained by other means; and the amount and quality of its residue after incineration sufficiently indicate its adaptedness to these purposes. No danger can, in general, be apprehended from the clogging of grates by slag at the moderate temperatures employed in open office or parlor fires.

The appearance of the residua lest, after reincinerating the waste materials of this coal, is very remarkable. Not a trace of redness is visible in that from the cinder. A grayish white is the color of the reduced ashes, and a light red predominates in the residue from the soot. It was remarked, in reincinerating the latter, that the part of the ashes lest which was at the top, became of about the color of wood ashes; while the lower parts, near the bottom of the platinum basin, were reddish brown.

No. 10.

Bituminous coal from Quin's run, Clinton county, Pennsylvania, sent for trial by Messes. McDonald & Hullenback.

This sample of coal was accompanied by the following letter:

"FARRANDSVILLE POST OFFICE,

"Clinton county, Pa., Quin's run, August 20, 1842."

"Some time since we shipped for your experiments at Washington four hogsheads of bituminous coal, marked 'Navy yard, D. C.,' to be transshipped at Columbia, Pennsylvania, to the seat of Government. We would thank you to instruct the proper persons having charge of the coals received for trial, to give attention to them, if not too late for the experiments.

"The coal marked No. 1 is différent from the others, and we believe

will be found a superior article.

"We have the honor to remain, gentlemen, very truly, your obedient servants,

"McDONALD & HALLENBACK."

"To the NAVY COMMISSIONERS,
"Washington, D. C."

The exterior characters of this coal are, a color almost uniformly shining jet black—except, of course, the faces marking the planes of deposition, in which the usual reedy matter, in the state of mineralized charcoal, gives a dull deep black, with numerous well-marked but small organic remains.

The main partings are well defined, and incline to the surfaces of deposition in angles of 85° and 95°. The cross partings are also, in many specimens, unusually well defined; smooth and brilliant plane surfaces, inclined to the main partings in angles of 88.5° and 91.5°, and to the surfaces of deposition in 70° and 110°. The coal thus separates into rhombic prisms.

Occasional specks of sulphuret of iron present themselves in the natural

partings.

The specific gravity of one specimen of this coal was found to be 1.3225, that of unother 1.3404; the mean of which gives the calculated weight of 1 cubic foot of solid coal equal to 83.22 pounds.

Nineteen trials in the charge box proved its average weight to be 50.335

pounds per cubic foot, or 0.6048 of its calculated weight.

The space for stowing 1 ton is 44.502 cubic feet. Of moisture, it contains, by the analytical operations, 0.646 and 0.557 per cent., as determined by two specimens. By trial in the steaming apparatus, the proportion of moisture was found to be 0.836 per cent.

One specimen examined for sulphur gave 0.1019 per cent. of that in-

gredient.

The volatile matter, other than moisture, was 17.791 and 17.071 for the two specimens above referred to; and the total volatile matter in two specimens examined by Doctor King was 17 for one, and 22 per cent. for the other. The average will not therefore be far from true, if assumed as 13.465.

Four incinerations of each of the first mentioned specimens gave a mean of 6.51 per cent. of earthy matter for the one, and 7.57 for the other. Hence the composition is as follows:

<b>N</b> oisture	•	- ;		•	-	-	-	Specimen <i>a.</i> 0.559	Specimen <b>6</b> - 9.679
Other volatile n	atter	-	-•	· •	-	· <b>-</b>	-	17.791	17.071

•	,				•			100.	100.
Volatile			•	, <b>-</b>	•	•	•	1:4.228	1:4.375

Besides the preceding analyses, a comparative trial was made on forty specimens; from each of which a fragment was taken, and a portion of the powder of the whole subjected to the usual steps for determining the constituents. This gave—

- ·										
Of moisture -	•	•	-	•	-	: -	-	-	•	0.131
Of other volatile m	atter	-	-	•	-	-	•	-	•	18.676

Of fixed carbon	•	-	•	-	-	• -	•	•	-	73.443
										-
									,	100.

Volatile to fixed combustible 1:3.93.

The ashes are almost perfectly white, whether procured from the single specimens, or from the mixture just described.

In burning 1,883.25 pounds of this coal, the residue from the furnace consisted of 143.26 pounds of gray ashes, weighing 37.09 pounds per cubic foot, and 25 pounds of slaty matter and clinker, weighing 29.7 pounds per cubic foot. Hence, the furner was 7.61, and the latter 1.327 per cent.; and the total waste 8.937 per cent. of the coal burned.

There were found in the ashes 7.577 per cent. of combustible residue, and in the clinker 9.512 per cent. Hence, the absolute waste from the furnace is 8.232 per cent. Six and three-fourths pounds of soot withdrawn from the flues, gave of volatile matter 16.03, carbon 35.32, and ashes 48.65 per cent.

The time required for the attainment of a uniform rate of evaporation is not precisely determined in the first experiment; but it was less than one hour. In the second it was but thirty minutes. Three-quarters of an hour is, therefore, a full allowance for this effect. The mean amount of coke left after each trial was 14.75 pounds.

A trial of specimen a, above analyzed, afforded, with oxide of lead, from 20 grains of coal 573.3 grains of lead, or 28.665 times its weight. Deducting the moisture and ashes found in that specimen, which amount to 7.069 parts, the lead to 1 of combustible is found to be 30.846.

Of the powdered coal from forty specimens, two trials by litharge were also made—each upon 10 grains of the mixture. The first gave 284.6, the second 285.5 grains of metallic lead. As the earthy matter and moisture are here 7.881 parts, the lead to 1 of combustible, by the first trial, is 30.894, and for the second 30.982. The mean of these three, viz: 30.907, may be assumed as the average reducing power of the combustible matter of this coal.

When tried in the chain shop, this coal was found eminently useful for that species of work. Sixty pounds of it were sufficient to make eleven links of a chain 15 inch in diameter. It gave but little cinder, and a flame of moderate length.

In the performance of ordinary smith work, to which it was applied in the anchor shop, the result was also highly satisfactory. It gave little cinder, a coke soft and yielding, and a form of fire abundantly hollow for all the purposes there required.

 $\cdot$   $\dot{b}$  .

#### Remarks on the three preceding tables.

By a reference to the two tables of experiments, LXXXVIII and LXXXIX, it will be seen that the rate of supplying water to the boiler \*during the period of steady action was, in general, very regular; and that the uniformity of rate extended, on the second trial, to an hour before and an hour after the limits assumed for steady action. But it did not commence till some time after the second charge of coal was all upon the grate, nor continue so late as when the last charge was all on. This renders it necessary, for the purposes of calculation, to assume the times specified at the foot of the table, for the commencement and termination of steady ac-The boiler, in fact, performed its office for 7½ hours on the second day, at almost exactly the same mean rate as during the 53 hours between the times of supplying the third and that of the ninth charge of coal. As all the times elapsed between consecutive sets of observations had the same length, (namely, half an hour,) the result of the single calculation for the whole time is, of course, identical with that of the mean of the separate calculations, as seen in the 22d and 23d lines of the table of deductions in the column of the first trial.

The 3d line of the last table shows that the grate was of the same size in both trials; the 11th, that the coal was supplied five per cent. more rapidly on the second than on the first; the 20th, that, on an average, 19 pounds more of water were evaporated per hour on the second; the 39th, that the gases escaped to the chimney with 20 degrees more of an excess above the steam in the boiler on the second than on the first trial; the 43d line proves that 0.11 of a pound more of water was evaporated by a pound of combustible matter of the coal on the second than on the first trial; and the 46th line shows that on the first trial the air plate was closed, and on the second it was open. The syphon showed the mean force of draught on the two days to be nearly identical. These facts appear to prove conclusively the advantage to this coal of air admitted at the bridge.

#### No. 11.

Bituminous coal from Karthaus, Cleanfield county, Pennsylvania, sent by C. S. McCoy & Company.

This sample was accompanied by a letter, of which the following is a copy:

"KARTHAUS, June 22, 1842.

"GENTS: According to your advertisement, and at your request, we have forwarded on to your department the quantity of bituminous coal you have required for a sample, although at considerable expense to get it to your place at this season of the year.

"We consider it a pleasure in forwarding samples of our coal to any part of the United States, not fearing but it will far surpass your expectations.

"We do flatter ourselves to think, from the trials already made of our coal, to say that we have the best bituminous coal in the world. All we ask is a fair trial. The coal we sent you was put in four hogsheads, marked from C. S. McCoy & Co.'s sample coal.' Two hogsheads were from the Karthaus, and two from the Salt Lick banks. We don't consider that there is any difference in the coal, as they are only one mile from each other; both on the west branch of the Susquehanna river. The coal we sent you was taken from the mine last.

"We can deliver any quantity of the coal at Port Deposit in the spring of the year, or as long as our river keeps up, which sometimes lasts three

months.

"If our coal should suit you, and we could agree upon the price, it would be necessary for us to know soon, as it will require a good deal of preparation to build arks, which would have to be done in part this summer and fall. From Port Deposit it could be delivered to any of the points on the coast you have designated in your advertisement.

"We can deliver our coal at port at about \$7 50 for 2,000 pounds. Our coal always sells on the Susquehanna river from 3 to 5 cents a bushel more than any other bituminous coal. We would like to hear from you as soon

as you make the trial.

"We refer you to General James Irvin, member of Congress from Centre county, Pennsylvania, who is personally acquainted with us and our coal. If you think it necessary, one of us could come into your place and make arrangements.

"Yours, with respect,

"C. S. McCOY & CO.
"per J. G. LEBO."

As to exterior characters, this coal has a columnar structure, parting with ease at the surfaces of deposition, so, which the main partings are at right angles. The cross partings are not, in general, well defined. The color is a deep black, and the mater dull or shining, according to the particular ply examined. The surfaces in the main partings exhibit frequent dakes of explonate of lime. Sulphuret of iron is occasionally found efflorescing among the carbonaceous matter in the horizontal partings.

The specific gravity of two specimens was 1.2918 and 1.2753, respectively; from the mean of which, the calculated weight in the mine is 80.22

pounds per cubic foot.

Thirty-five trials in the charge box proved the average weight per cubic foot, in the state in which it was received, to be 52.542 pounds—the extremes being 49.375 and 56.625, of which the mean is 53 pounds, or 0.6549 of the calculated weight.

The space required for 1 ton is 42.634 cubic feet.

The moisture expelled from the two specimens above tried was found to be 0.77 for the first, and 0.952 for the second. This was effected by exposing the powder to a temperature of 216° for more than an hour in the apparatus seen at plate 1, fig. 1.

By drying in the apparatus K, (Plate II, Fig. 1,) connected with the boiler at the navy yard, the loss on 28 pounds was 5% ounces, or 1.282 per

cent.

The per centage of volatile matter, other than moisture, was found, by rapidly coking the first specimen, to be 21.5 per cent.; and by coking so slowly as to prevent agglutination of the particles of coal, it was but 13.06 per cent. The second specimen gave, by a mean of two trials, both per-

formed rapidly, 11.881 per cent.

Dr. King obtained from two specimens a mean of 23.25 per cent, of volatile matter. The mean of trials on four specimens gives the total volatile matter 19.23 per cent. Hence it appears that the Karthaus coal is superior in the amount of its volatile constituents to any of the free-burning coals hitherto examined. But its principal constituent is still the fixed carbon, which, for the least amount of volatile matter obtained by slowly coking the first specimen, was  $\frac{80.993}{13.06}=6.124$  times as much as the latter ingredient; but by rapid coking, the ratio was reduced to  $\frac{72.648}{21.36}=3.378$ .

The incineration of each specimen was made in the same manner as of other samples. Specimen a gave 5.087, and specimen b, 6.68 per cent. of

reddish-gray ashes.

In one hundred parts, therefore, there were in

•			•	Specimen a.	Specimen b.

During the four trials on evaporation, the total weight of coal burned was 3,643.84 pounds, which produced of clinker 136.71 pounds, and of ashes 188.73.

The ashes, by complete reincineration, lost 12.6 of their weight, and the clinker was reduced to 2.13 per cent. by the same means; so that the absolute amount of waste withdrawn from the furnace was 255.05 pounds; of which the part in the state of clinker was 52.46 per cent., and the whole was 7 per cent. of the coal consumed. The ashes weigh 47.94 pounds per cubic foot, and are, when completely freed from carbon, of a light reddishgray color. The clinker weighs 32.75 pounds per cubic foot, and is of a dark-brown and iron-black color, with yellowish shaly portions. It is in small fragments, porous in texture, and not so much agglutinated as to cause very serious obstruction to the passage of air.

279 [ 386 ]

The large proportion of clinker is in part accounted for by the presence of sulphuret of iron in such quantity as to yield 1.58 per cent. of sulphur

from the specimen a, above analyzed.

The accendibility of this coal (that is, the degree of readiness with which its combustion commences) is indicated by the fact that it required on an average 14 hour to bring the boiler into steady action after the charging with coal had commenced.

The weight of coke withdrawn after each trial was, on an average, 8.578

pounds.

A trial of specimen a by the oxide of lead resulted in reducing 31.328 times its weight of metallic lead; and this, deducting the incombustible ma-

terials present, gives for 1 of combustible, 33.309.

This coal was tried for its general adaptation to smithing purposes, both in the chain and anchor shops, where it was found to give a good hollow fire, preserving the arch without danger of disturbance from the blast, and to produce a clear and effective welding heat. The coke is not quite equal for sustaining a good durable fire to that from some other coals of the free-burning class.

In a well-set office grate, with a good draught, it was found to require considerable time for ignition, kindling slowly at the bottom. More than an hour elapsed before any considerable activity of combustion had been attained. While any of the vaporizable and gasefiable ingredients of coal remain, the mass will remain mostly black. White or yellowish vapors continue to be given off at the top of the mass; and even if temporarily ignited, by bringing any flaming body in contact with these gaseous materials, they will generally burn but fitfully, and their inflammation will last no longer than the torch with which they are attempted to be ignited is kept in contact with the issuing current of mixed vapors and gases. It will be seen, on consulting the tables of experiments with that of deductions following them, that some difference in evaporative power was observed while using different casks of the sample; but, as the two localities from which they came were not designated, the whole is, of course, taken as a single sample.

In coking rapidly, this coal discharges gas copiously, intumesces strongly, forming a coherent porous mass, moderately tough, and of a steel-gray color. By coking more slowly, the consistence is more compact and tough; and by very slow treatment, the powder is scarcely rendered in any degree coherent. The coke of this coal is well adapted for smelting iron.

The period of steady action is from 10k. 10m. a. m. to 5k. 40m. p. m. = 7k. 30m.; coal supplied to grate, 636.5 lbs.; water to boiler; 5,558 lbs.; water to 1 of coal, 8.738. This being the first experiment of the series, less regularity in the supplying both of coal and of water is observable, than were found practicable after a little training and experience on the part of the firemen and other assistants.

ish-white shaly portions adhering to such as are more fully vittified. It is

cemented into large porous masses.

The soot collected from the flues after burning this coal weighed but 7.83 pounds per cubic foot, and lost by complete incineration 55.86 per cent., leaving of course 44.14 per cent. of reddish-gray askes. The total weight of soot was not exactly ascertained. The quantity was moderate.

The effect of the clinker from this coal in impeding the draught, and rendering the combustion irregular, will be understood from an inspection of the tables of combustion, in which wide differences will be observed between the evaporation at one period and that at another. The large proportion of clinker to the total waste might lead us to expect that much

reduced. This is confirmed by an experiment sed, which gave 1.5 per cent. of sulphur.

y oxide of lead resulted in giving 28.127 times, deducting the moisture and earthy matter, it power of the unit of combustible matter in this

e described afford the following composition for

Moisture Sulphur - Other volatile r Ashes - Fixed carbon	naiter		-		8pecimen a. 0.700 1:500 18.195 15.360 64.245	Specimen & 1.105 (not tried.) 20.255 9.050 69.590
Fixed to vols	ıtile con	nbusti	ible	•	100. 9.535:1	3.435:1

Treated with scale oxide of copper, 7.26 grains of specimen a, well dried, afforded of carbonic acid 20.62 grains, equivalent to 5.6236 grains of carbon; and 3.23 grains of water, equivalent to 0.3588 grain of hydrogen. The ashes are 15.762 per cent. of the dried coal, or 1.1444 grain, leaving for oxygen and azote 0.1332 grain. Hence the combustible matter alone is 6.1156 grains; and, excluding the earthy matter, the several constituents have to each other the following relations, viz:

Carbon	•	-	•	-	-	-	91,955
Hydrogen	-	-	-	-	-	_	5.867
Oxygen and	azole	-	•	-	-	-	2.178
• -		•	•				
							100.

Of this combustible matter, if the heating power be computed from that of its carbon alone, it amounts to 0.91955 × 12906=11868; and the evapo-

rative power to 11868 + 1030=11.522.

The table of deductions shows that the evaporative power of 1 of combustible matter, as applied to the boiler, was, on an average, 10.238. If this number be increased by adding the heat expended on the air which supplied the furnace, the moisture of that air and the water generated in combustion, and which was proved in the case of a coal of analogous properties (that from Quin's run) to have been 12.823 per cent as much

as was absorbed by the boiler, then will the evaporative power of the unit of combustible matter be represented by - 11.550
 While, as above, that of the carbon is - 11.522

It was found to come rapidly into combustion, and to afford an intense heat. A large bolt, which had just before been brought to a good working heat by coal in ordinary use in the yard, was by that now under consideration brought to the same degree of heat in ten minutes less time. The compactness of the coking mass appeared to be sufficient to form a good hollow fire for work of the size now performed by it. The cinder taken out was stated to be far less than that given by coal in common use at that time. The workman stated that he had been working in the yard for six years, and that this was the best coal, for the work he was then engaged on, which he had used in all that time. Two other workmen tried each a small portion of it, and both commended it very highly.

The smoke, while using this coal, was observed to be far less than that from any of the other fires (of which some ten or a dozen were in action) using the ordinary coal of the yard. The only fault is the lightness of the

coke, which requires the fire to be frequently "wetted down." = 0

In the chain shop, the workmen spoke of the same inconvenience from lightness of the coke. But on a small chain it was found to work well, giving very promptly a good welding heat, without interference from forcign matter. The cinder was stated to be about half as much as would be obtained in the same time from the coal now in general use, (the Midlothian.) Freedom from smoke was here remarked upon with approbation by the workmen, and was very conspicuous among the large number of smoky fires then in use at the same shop.

· The amount of volatile matter in this coal is too small to commend it for

use in procuring illuminating gas.

For domestic purposes, it may be employed in open grates with great ad-

vantage, on account of the clear combustion of its gaseous products.

The accendibility of this coal does not appear to be equal to that of some of the other free-burning class—it having required two hours, on an average of the four trials, to bring the boiler into steady action. By a like average, it also appears that there were withdrawn from the grate, after combus-

tion had ceased, 14.812 pounds of unburnt coke.

In the table of deductions, following those of the experiments on evaporation, it will be observed, that though the weights of coal actually consumed at the several trials were very different, (being in one case 1,271.25, and in another only 331.25 pounds,) yet that the evaporative effects of the pound of coal are all very near each other; a circumstance which indicates the reliance to be placed on the method of determining the relative heating powers of fuel adopted in this research. Though all fine, it was observed to form a slightly coherent coke, which, on being broken up with the slice iron, allows a free passage to the air, and favors a brisk combustion.

#### Remarks on the preceding synoptical table.

In reference to density, the above table proves that the mean weight per cubic foot of the six samples from Maryland is 53.137, and that of the six from Pennsylvania 52.551 pounds; or the average of the whole is 52.844. This is 0.506 pound less than the average weight of eight samples of anthracite, as seen above, at page 181. The space for the stowage of one ton is 42.4 cubic feet.

The average evaporation of water per cubic foot of coal from 212°, by eleven samples of the free-burning bituminous class, is 510.35 pounds; while the average for eight samples of anthracite, as seen in page 180, is 509.93. In regard, therefore, to this property, the two classes may be con-

sidered, to all intents and purposes, identical.

The average number of cubic feet of water supplied to the boiler per hour, while testing the free-burning coals, is shown in the last column but one, on page 305, to have been 13.726; while from the corresponding column of page 179, it will be seen that the average for eight samples of anthracite was 12.003 cubic feet, showing a difference in favor of the free-burning class of 1.723 \(\div \) 12.003 = 14.35 per cent. When compared, however, with the two samples of artificial coke, as given with the anthracites, at the page last cited, and of which the mean evaporation was 15.708 cubic feet per hour, even the free-burning coals are seen to be inferior to the cokes. Thus 15.708—13.726 = 1.982 cubic feet, which is 14.44 per cent. of the rate of evaporation by the coals. This circumstance justifies the use of coke in locomotive boilers, in preference to any other fuel, where the price does not interfere to prevent it.

The superior rapidity of action by coke is explicable from the known fact of its porous texture, and the ready admission of air to a vast extent of surface for combustion, resembling, in this respect, the cells in the lungs of animals, which are so admirably fitted to expose large surfaces for the rapid absorption of oxygen in the analogous process of respiration. Coals which contain considerable quantities of vaporizable incombustible matter, such as water and salts of ammonia, or earthy and other carbonates decomposible by heat, are constantly generating, while in combustion, substances which not only, when in contact with the fuel, interfere with rapid combustion, but in the flues occupy the space which would otherwise be left for the true products of combustion to escape with more

ease and rapidity.

Having exhibited, in respect to the anthracites, the steam-generating and the lead-reducing power of the unit of combustible matter of each sample in parallel columns, I may here arrange the free-

burn	ing coals in reference to the same sets of results. They stand as	follows:	_
	Coals.	Steam to 1 of combustible.	Lead reduced to 1 of combustible.
_	A 11	71.694	20.000

In examining the right-hand column, or reductive powers, of the above table, we perceive that the numbers do not conform, or even approach, to the order of those expressing the evaporative powers, but rather tend to the reverse order; and this is true whether we compare the free-burning

coals among themselves or their whole class with that of the anthracites.

In confirmation of the general fact that anthracites exhibit a higher reductive power than any of the bituminous class, I may cite the experiments of M. Baudin, who found the mean reductive power of the combastible matter of the anthracites of Charbonnier, (Biassac,) Messeix, (Haute Dordogne,) and Chambled, (Commentry,) to be 33.52, which is between the results that I obtained for the Lackawanna and Peach Mountain anthracites; and for three different free-burning bituminous coals, (those of Lacombelle, Deux Chaises, and Les Barthes,) varying in volatile matter from 17.7 to 20.2 per cent., he obtained a mean reductive power of 31.393.

<sup>\*</sup> Annales des Mines, tom. 1, 4me serie, 1842, pp. 87, 90, 92, 94.

#### CLASS III

BITUMINOUS CAKING COALS FROM THE EASTERN COAL FIELD OF VIRGINIA,
IN THE NEIGHBORHOOD OF RICHMOND.

#### SAMPLES.

- No. 1. Barr's Deep Run.
  - 2. Crouch & Snead's.
  - 3. Midlothian 900 feet shaft, (average.)
  - 4. Creek Company's.
  - 5. Clover Hill.
  - 6. Chesterfield Mining Company's.
  - 7. Midlothian average.
  - 8. Tippecanoe.
  - 9. Midlothian "new shaft."
  - 10. Midlothian screened.
  - 11. Midlothian, (navy yard, Washington.)

#### General characters.

The range of specific gravities in this class is nearly the same as in that of the free-burning coals; but the average is rather less. The average weight per cubic foot is also less by about 3.5 pounds. These coals burn with a long flame and much smoke—giving an intumescent, coherent coke, preserving nothing of the original form of the coal.

#### No. 1.

was coal from Deep Run wines, in the neighborhood of Richmond, Virginia, sent for trial by John Barr, Esq.

apanying this sample was the following letter from the proprietor:

"RICHMOND, October 10, 1843.

AR Sin: Having been informed, through J. R. Anderson, Esq., that donly a small portion of the sample of coal sent by me to the navy ome time ago, I now beg leave to hand you annexed bill of lading ir hogsheads of Deep Run coal, shipped per the schooner Wm. H. in, on which I have paid the freight.

on will confer a favor by testing its qualities; and I should be glad if

buld inform me of the result at your convenience.

"Respectfully, your obedient servant,

"JOHN BARR, "per J. J. VAUGHAN.

tofessor Johnson, \* Navy Yard, Washington."

eides the four hogsheads of the coal mentioned above, a single hogs-, left from a sample previously received at the yard, was included in the sample tried for evaporative power, and its effect is given in the table of the fifth trial.

The exterior characters of the Deep Run coal are a jet-black color and shining surface, particularly in the main partings. The distinctness of these, and their nearness to each other, give the coal the appearance of be-

ing foliated.

In this, as in several of the bituminous coals of Pennsylvania, the main partings are at an angle of 85° with the surfaces of deposition. The fa-. cility with which the coal separates at the main partings, causes it to fall mostly into small pieces; and this circumstance gives the average weight per cubic foot probably somewhat higher than it would have been had the whole been in the state of lumps. The cross partings give rather irregular surfaces; but there is a general tendency to form rhombic prisms.

The specific gravity of two specimens, a and b, was 1.4023 and 1.3628; from the mean of which, the weight of a cubic foot of solid coal is 86.41

pounds.

During the experiments on evaporation, 48 charges, of 2 cubic feet each, gave, as the mean weight per cubic foot, 53.174 pounds. Hence the actual weight, in the condition in which the coal was received, is 0.6158 of the calculated weight from specific gravity. The space required for 1: ton is 42:126 oubic feet.

The moisture expelled in drying portions of the two specimens was for a 0.75, and for b 0.5. In the steaming apparatus at the navy yard, 28 pounds lost in four days 8 ounces, or 1.785 per cent. The last in fraction of the first in the second of the secon

The volatile matter, other than moisture, from specimen a was 1918 and from 6 19.2. The earthy matter in a was 14.919, and that in 6 only 5.086; Hence the fixed carbon in a is 65.191, and in b 75.214. Volatile to fixed combustible 1: 3.392; and 1: 3.917.

Besides the preceding analyses, an experiment was made on about forty

fragments from as many different specimens of the coal, (some from each cask) which gave the following result:

Moisture -	•	•	•	-	<b>***</b>	0.628
Other volatile matter	•	•	•	•	•	19.782
Earthy matter -	•	•	•		•	11.468
Fixed carbon -	•	•	-	•	•	68.122
'						100.

Hence it appears that the fixed is to the volatile combustible as 68.122:19.782=3.443:1.

The coke of this coal, when produced rapidly, is intumescent; and the vessel in which the coking process is performed is represented by a cast which fills the interior; and the mass, on being cut through, exhibits distinct concentric layers, indicating a succession of stages in the process of coking. The vacant spaces between the concentric shells are less in amount than the solid parts of the mass.

The ashes, from analysis, vary in color from yellowish white to nearly flesh-red; those from the mixture of forty fragments are of a very light fawn color.

During the five trials on evaporation, there were burned 5,072.75 pounds of this coal; and the total waste from the furnace in the state of ashes was 319.39, and in clinker 244 pounds. From the flues were obtained 21.5 pounds of soot.

The ashes gave by reincineration 12.1 per cent. of combustible matter, the clinker 0.873, and the soot 54.71 per cent. This reduces the total incombustible residuum from all these sources to 531.35 pounds, or 10.475 per cent of the coal burned.

The following may, therefore, represent the proximate constituents of this sample by the large analysis actually carried on, in part, in the furnace, viz:

Moisture, by drying 25 pounds -	-	- 1.785 per cent.
Other volatile matter, from 40 specimens	-	- 19.782 "
Earthy matter, from 5,072.75 pounds	· <b>.</b>	- 10.475 "
Fixed carbon, by difference -	-	<b>-</b> 67.958 "
•		
		100.

Which gives the volatile to the fixed combustible 1:3.4354.

The ashes weigh 44.86, the clinker 33.5, and the soot 12.23 pounds per enbic foot. The clinker is in large black porous masses, evincing much fusibility, glazing and incrusting the shaly and other foreign matter mixed with it. It manifests some tendency to spread out into sheets, but does not attach itself with any considerable force to the grate bars. When pulverized and completely calcined, its color becomes a dark brown, while the residuum from the ashes is of a red gray, and that from the soot a lighter red, nearly approaching to fawn-colored.

A trial of specimen 6 with oxide of lead resulted in reducing 24.94 times its weight of metallic lead. This, after deducting earthy matter and moisture, shows the combustible ingredients to possess a reducing power of

26.416. Quantity of coal essayed, 20 grains.

Fearing there might be some source of error in the preceding trial, I took a portion of the mixture of 40 specimens, performed the experiment with caution, and obtained 24.62 times its weight of lead. Goal used, 10 grains; lead to 1 of combustible, 28.007.

In the chain shop, this coal burned with a long flame, with no extraordinary amount of smoke, gave a lively heat, and was pretty well adapted to making chain. Sixty pounds of it put in eight links of -1 15 inch chain. The coke is light, and rather difficult to be kept in place before a strong blast.

In the ordinary smith work, to which it was applied in the anchor shop, it was found "a strong coal," making a hollow fire, which stood a long time.

The amount of volatile matter is insufficient to render this a suitable coal for gas-making purposes. For domestic applications it possesses the quality of giving a lively fire, with much less smoke than most other samples from the Virginia coal field to which it belongs.

The accendibility of the coal is indicated by the lengths of time taken to bring the boiler to steady action, which, in the several trials, were as follows:

First trial -	• • •	•.				1.416	hour.
Second trial	• '	• • ,		•		1.700	<b>a.</b>
Third trial -	•	•	• •		· •	1.400	<b>66</b> .
Fourth trial	•	,. <b>-</b>	. •	· 1 •	r <b>-</b>	1.588	<b>66</b>
Fifth trial '-	•	•		· • ·	,, •	1.500	<b>66</b> , }

Mean - - - 1.520 ' or 1 hour and 31 minutes.

The mean weight of coke left after each trial, besides what passed the sieve and was weighed with the ashes, was only 6.4 pounds.

Possed of steel to the control of th

Period of steady action, from 0h. 50m. to 5h. 46m. p. m. = 4h. 56m.; coal supplied to the grate, 506.3 lbs., water to the boiler, 4,168.4 lbs.; water to 1 of coal for the same period, 8.229. The column of "remarks" will show the cause of suspending the supplying of water for a portion of the time between 2h. 30m. and 4h. 30m. p. m; the evaporation, however, still proceeded at about the average rate.

#### Remarks on the preceding table of deductions.

The combustion of this coal evidently produced a pretty rapid as well as uniform rate of evaporation; and this circumstance, as well as its composition, entitles it to rank, if not umong the free-burning class, at least in near proximity to those which have been thus denominated. It belongs to a place intermediate between those which in France are designated as dry coals with short flame, and those called fat coals with short flame.\*

The average rate of evaporation per hour, (13.421 cubic feet,) as found in the 21st line of the table, differs from that of the free-burning class by

only three-tenths of a cubic foot.

The fifth trial of this coal afforded an opportunity of studying the influence on the economy of fuel of working at an increased pressure, as had been done in the case of the Peach Mountain anthracite. The effect is entirely in accordance with what was given in that case; and the observations on temperature of escaping gases, in the 30th and 39th lines of the table, point significantly to the cause of the inferiority of the result. Not only was the temperature of the escaping gases absolutely higher at the high than at the low pressure experiment, but, relatively to the temperature of steam in the boiler, it gave a greater excess of temperature over the high steam than it had over the low. Thus, on the fifth day's trial, (the 28th of October,) the steam was at a mean temperature, during steady action, of 258°.37, and the escaping gases at 371°.31: difference, 112°.94. At the third trial, (on the 25th of October,) the damper and air plate being in the same condition as on the 28th, the mean temperature of escaping gases was 337°.29, and that of the steam 231°.82; and their difference 105°.47. Now, 112.93—105.47—7°.46—the excess of difference on the day of working high steam above that of using it at the ordinary range adopted for the experiments. This small excess may possibly be assignable to the coating of soot which had accumulated in two days. If, however, the whole of the superior temperature of the gases be due to the higher temperature maintained in the boiler, its effect in diminishing the evaporative effect of the unit weight of fuel can readily be computed from data actually obtained while burning this coal. On the 25th of October, the analysis of gases entering the chimney proved that 19.965 pounds of air passed through the fire while burning a pound of coal; and that the dry gases, from the combustion of a pound of coal, were equivalent, in capacity for heat, to 20.477 pounds of air, or to 5.465 pounds of water. Hence, by heating those gases to 371°.31, instead of 337°.29, or 34° hotter in one case than in another, a heating power is expended on the gases, and lost to the boiler, of 5.465X 34=185°.81; and this divided by 1030 gives 0.1804, as the evaporative effect of the temperature imparted to the gases in the one case more than in the other. If the first trial be compared with the fifth, the difference in temperature of escaping gases is 371°.31—280°—91°.31; and this multiplied by 5.465, gives 499 as the excess of heating power, or 0.4845 of evaporative power expended on the gases in the fifth trial above that in the first

No. 2.

Bituminous coal from Crouch & Snead's mines, Henrico county, Virginia.

No letter or certificate accompanied this sample of coal. A memorandum on the bill of lading merely signified that it was from the above-named mines, and that their distance from Richmond, by James and Kenawha

river canal, is 12 miles.

In exterior appearance, this coal is either columnar or foliated. The alternate plies of bright and dull matter are generally very thin. The main partings are inclined 85° to the surfaces of deposition. The cross partings are not well defined. On the main partings are occasionally seen efficiences of sulphate of iron; and along the lines are cracks, manifesting the effect of the air, which, in less than eighteen months, has begun to disintegrate the coal by the decomposition of its sulphuret of iron.

The specific gravity of specimen a of this coal, which I analyzed, was found to be 1.4513, and that of b 1.8347; the latter being of a very sluty appearance. This gives the mean weight of one cubic foot of the solid coal 107.69 pounds; but taking a alone, it would be but 90.71, which I

am inclined to adopt as the weight of the true coal.

The mean result of thirty-six trials in the charge box is 53.593 pounds per cubic foot; the highest number being 56.378, and the lowest 50.5, of which the mean is 53.437. Hence, the calculated is to the merchantable weight as 90.71:53.593=1:0.5908. The space to receive one gross ton is 41.797 cubic feet.

The proportion of moisture obtained from analysis of specimen a was 0.957, and that from b was 0.955 per cent. From 28 pounds, exposed for three and a half days in the steaming apparatus, were expelled 8 ounces, or 1.785 per cent. of moisture. Of other volatile ingredients, besides moisture, a gave 26.103, and b 22.895 per cent.

Dr. King obtained from one specimen 27.25, and from another 21.5 per cent. of volatile matter, including moisture. Hence, deducting for these two the same proportion of moisture as found in the other specimens, we

have the volatile combustible matter as follows:

•	Specimen a		•	•	•	•	26.103
	Specimen b		•	•	•	•	22.895
Dr. King's	Specimen c	•	•	. •		• ,	26.994
trials.	Specimen d	• •	•	•	• '	. •	20.544
		,	•		~	•	-
:	Mean -	٠.	•	•	•	*	23.959

Of sulphur, specimen b afforded 0.4271 per cent.

Four incinerations of specimen a gave 8.72, and one of b 41.56 per cent. of incombustible matter, of a dirty white color, slightly tinged with red. A

trial on the purer plies of à gave but 6.22 per cent.

During the trials of evaporation, 3,834.75 pounds of coal burned, yielded of ashes 346.406, and of clinker 205.94 pounds. On reincingration, the former lost 7.208 per cent. of their weight, and the latter 0.95 per cent. Of soot and dust, after all the trials, there were obtained 34.75 pounds, of

which 66.49 per cent. was incombustible matter. The three reductions being made, show of incombustible matter—

From the ashes, to be	e -	•	•	- 321.438 pounds.
From the clinker "	•	•	•	- 203.091 "
From the soot "_	•	. •	•	- 23.105 "
•				
Total	•	•	•	- 547.634 "

This is 14.28 per cents of the coal consumed, proving that the first specimen analyzed was possessed of considerably less impurity than the average of the sample, and the second of nearly three times as much as its average proportion. In fact, specimen b is a highly bituminous slate, of which no small quantity occurred in the sample, showing a want either of skill or of proper care in the mining.

The clinker of this coal is much vitrified; the surface reddish brown; the interior, when broken, black; masses of considerable magnitude occur, with much shaly matter, variously colored, light, and porous. The clinker weighted 29.87 pounds per cubic foot, the ashes 40.92, and the soot 25.51

pounds.

From specimen a

Earthy matter	of opera					• • •	14.280

If the grant that the four analyses above made give the true proportion of gatebous combustible, the average of the fixed carbon will be 83.935—23.959—59.976; and the volatile to the fixed combustible matter as 1:2.499. Twenty grains of specimen b, treated with 1,200 grains of oxide of lead, reduced 393.9 grains, or 19.695 times its own weight of metallic lead. A repetition of the experiment gave 19.54 times its weight.

In the anchor shop this coal produced a good hollow fire, worked well, but gave a rather large amount of cinder. The pieces of work were not of such magnitude as to require a large fire; hence, the full exhibition of its power to sustain the hollow condition of the fire was not probably called forth.

In the chain shop, so pounds proved sufficient to put in s links of He shain. The cinder was abundant; the flame much like that of the Midlothian coal. In this shop there is no necessity of producing a hollow fire, the ends of the links being heated in close proximity with the tuyers.

In an office grate the ignition was rather tardy, owing to the fineness

of the coal; but, when once ignited, the coke cohered, and a brisk, cheerful blaze was emitted, exhibiting rather less brilliant jets of flame than some others of the Virginia coals.

The time required to bring the boiler to a uniform rate of action was as

follows:

		•					h. m.
Pirst trial	•	•	•	<b>●</b> .	•	-	1 10
Second trial	<b>:</b>	•	•	•	•	-	1 15
Third trial	•	•	-	• .	•	•	Y OO
Fourth trial	•	•	•	•	•	•	1 13

or the mean time was 1.158 hour.

The quantity of unburnt coke was, on an average, exactly six pounds. The pulverized and recalcined clinker is of a dark reddish-gray color, the ashes lighter, and the residue of the soot still lighter than that of the ashes.

In coking, this coal emits a red smoky flame, loses every trace of its original form, swells very much, and leaves a mass jet black, shining, and friable. This is the result of a rapid application of heat. When put into a muffle perfectly cold, of which the temperature was very gradually raised to ignition, scarcely any cohesion of particles was produced.

Period of steady action, from 9h. 45m. a. m. to 5h. 30m. p. m. — 7h. 45m.; coal supplied to grate, 762.75 pounds; water to boiler, 5,430 pounds; and water to one of coal, 7.119. The rate of steady action might, perhaps, with nearly equal propriety, be assumed to commence at 8h. 25m. a. m., when the second charge had all been placed on the grate.

& SNEAD'S COAL.

open; coking plate on; air plates open.

Time each charge was on grate.	Dew point, by calculation.	Gain of temperature by the air before reaching grate.	Difference of temperature between steam and escaping gases.	Water per square foot of absorbing surface per hour.	REMARKS.—Grate surface 10.82 square feet; length of circuit of heated gases 121 feet; height of chimney 63 feet; a steam pipe extending up the chimney to within three feet of top of brick work.

No. 3.

# Bituminous coal from the mines of the Midlothian Coal Company, taken from a shaft 900 feet deep.

This sample was not accompanied by any written description, except the labels on the casks, which indicated the origin above described.

It is externally characterized by a lustre, either dull, resinous, or shining, according to the faces which are observed. The main partings, at right angles to the surfaces of deposition, are usually shining; those surfaces themselves are dull or resinous, but polished portions sometimes occur, giving the impression of having been rendered smooth by intense pressure and a sliding motion.

In the parting seams, thin plies of carbonate and of sulphate of lime fre-

quently occur.

The specific gravity of two specimens of this coal which I analyzed was for a, by two trials, 1.511; and for b, 1.2889—the former giving for the weight of a cubic foot of solid coal in the mine 94.435, and the latter 80.662 pounds.

By the mean of 34 trials in the charge box, the weight of a cubic foot, in the state in which it was received, was 50.518 pounds; the highest being 53.375, and the lowest 48.375; of which two, the mean is 51.375; so that the actual is but 0.5349 of the first calculated weight, and 0.6263 of the second.

The space required for the stowage of a ton is 44.341 cubic feet.

In the steaming apparatus, 28 pounds lost 5½ ounces, or 1.1719 per cent. of moisture.

The volatile matter, including moisture, in specimen a was 27.06, and that in b 29.84 per cent.

The ashes of a are 21.25 per cent., of a chocolate-brown color; and those of b 6.08 per cent., of a reddish gray.

Bringing together these results, we find them as follows:

Specific gravity -	-	-	. •	Specimen <i>a.</i> . 1.511	Specimen b. 1.2889
Moisture -	•	-	•	1.1719	1.1719
Other volatile matter	• .	•	-	25.8881	28.6681
Earthy matter -	, .	-	•	21.2500	6.0800
Fixed carbon -	•	•	-	51.6900	64.0800
•			•	100.	100.
Volatile to fix	ed com	-	1:1.996	1:2.235	

During three trials on evaporation, the quantity of coal actually consumed was 3,417.5 pounds; and the amount of ashes yielded was 143.75 pounds, weighing 53.51 pounds per cubic foot; of clinker 221.75 pounds, weighing 43.37 pounds per cubic foot; and 14.2 pounds of soot, of which 5.74 pounds made a cubic foot.

The clinker is in lumps of a large size, black, and porous, with some tendency to spread into sheets, tenacious and compact, embracing but little

light-colored shaly matter.

By complete reduction of the combustible matter of these three residua, the

Ashes lost 9.687 per cent., leaving 129.82 pounds. Clinker " 0.000 " " 221.75 " 56.630 " 6.13 "

Total absolutely incombustible matter=357.70

And this is 10.467 per cent. of the coal burned. Hence the sample was composed of—

Moisture (from 28 pounds) - - - 1.1719 per centOther volatile matter (from mean of two specimens) - 27.2781 "
Earthy matter (from 3,417.5 pounds) - - 10:4670 "
Fixed carbon (calculated by difference) - 61.0830 "

100.

Hence the volatile is to the fixed combustible 1:2.239

The reincinerated or calcined clinker produced a light brown powder, gaining slightly in weight by the treatment.

The ashes gave a reddish gray residue, and the soot one of a dark fawn

color.

Twenty grains of specimen b, with the oxide of lead, yielded 500.7 grains of metallic lead, equal to 25.035 times its own weight. Deducting the moisture and earthy matter, (7.252 per cent.,) the lead to i of combustible is 26.993.

In the chain shop, 60 pounds were sufficient to put in 8 links of a chain 114-inch in diameter. In the common smith work of the anchor shop, it was observed to produce a fair hollow fire; gave a clear white, but short flame; affording a good heat for welding iron and steel together, which was the work in hand at the time the trial was made.

The sample was in rather too fine a state for use in an office grate, but by a little management it gave a brilliant and active fire. After the coal has become well heated, brilliant jets of flame are frequently emitted.

The coke is of a coherent intumescent character, occupying considerably

more space than the coal from which it was formed.

The average time required by this coal to bring the boiler into uniform action, was 1.383 hour.

The average weight of unburnt coke was 5.917 pounds.

By reference to the table of deductions, it will be observed that the proportion of clinker to the total waste derived from this coal was more than 60 per cent.; which might readily indicate the probability of its offering considerable obstruction to the combustion, especially after a few hours' operation. Such was the fact; masses or plates 15 or 18 inches in diameter were drawn out.

When not impeded by an accumulation of clinker, the combustion is free, with a large red smoky flame. The clinker has some tendency to adhere to the grate bars, and keep them at a cherry-red heat, which induces warping and displacement.

6 1598 Open.	6.222	the absorbing surfaces of the boiler, and the consequent higher tem- perature at which the gases arrived at the chimney, and in part

#### Remarks on the preceding experiments and deductions.

By admitting the air which supplied the combustion to come at once to the grate, at an average temperature of 73°.2, on the third trial, instead of going round the furnace, gathering the waste heat from the stack, and arriving at the grate in the rear of the closed ash pit with a temperature of 230°.2, as in the first experiment, the following effects appear to have resulted: First, The rate of combustion was increased from 122.8 to 127.6 pounds per hour. Second, The rate of evaporation was diminished from 15.93 to 13.71 cubic feet of water per hour. Third, The gases arrived at the chimney, after a circuit of 121 feet in horizontal flues, at a temperature of 379°, instead of 319°, as on the first-day of trial. Fourth, The evaporative effect of the coal, as seen in the 41st line, was reduced from 8.892 to 8.102; and that of the combustible matter alone, as found in the 43d line, from 9.916 to 9.136.

The comparison is made between the first and third trials, instead of the mean of the first and second, and the third; because the first and third were both conducted with the air plate at the furnace bridge open, whereas

the second experiment was made with that plate closed.

Admitting that the air which passed through the furnace on the first and third days of trial was equally well employed, and equally deoxygenated, a computation founded on the analyses of the gases on the third trial, (table CXV,) may readily be made, which will show what was lost in burning with cold air instead of hot. Those analyses proved that, on an average, the weight of air equivalent in specific heat to the dry gases passing to the chimney during the combustion of a pound of coal, was 18.452 pounds. The waste matter from the furnace on that day was 11.32 per cent. Hence the weight of air equivalent to the gases from a pound of combustible matter is 20.81 pounds; and as the specific heat of air is 0.267 that of water, the equivalent weight of the latter material is 5.555 pounds. The heat imparted to the air and products of combustion on the third trial was 379°—79°.2=305°.8, which, multiplied by 5.555, gives 1698.9 as the heating power, or 1.649 as the evaporative power of this quantity of heat.

On the first day's trial, the air entered the grate at 230°, and the gases left the boiler at 319°, carrying away an excess of 89°. The total waste that day was 10.33 per cent., as seen in line 13 of the table. Hence the equivalent in air to the gaseous products from a pound of combustible metter, is 18.452÷0.8967=20.58; of which the heat absorbing power is by a similar computation 489, and the evaporative power equivalent to this is 0.475. The difference 1.649—0.489=1.160, added to the number 9.136 found in the 43d line of the table of deductions, gives 10.296; showing that the inferiority of the third to the first result (9.916) is rather more than compensated for by the cause now under consideration. Such, in fact, ought to be the case; since the fire doors were not kept open on the third trial quite to the end of the experiment, being closed at 4h. 30m. p. m. They were also closed for 43 minutes during one of the experiments in drawing gases from the chimney.

The 36th line of deductions shows that the average height of the draught gauge was 0.373 inch on the first trial, and 0.389 on the third. This is fully accounted for by the superiority in temperature of the gases on the third

trial over those on the first, for 379°—319°=60°.

#### No. 4.

Bituminous coal sent for trial by the Creek Coal Company, Chesterfield county, Virginia.

The following letter accompanied this sample:

"RICHMOND, June 27, 1842.

"Six: In compliance with the invitation of the Secretary of the Navy, I have sent by the schooner Pioneer five hogsheads containing two tons Creek coal, for experiment at your yard, with a view to test its fitness for generating steam on board the Government steamers.

"As there are other coals on board the vessel, you will oblige me by di-

recting it to be kept separate.

"This coal is raised by the Creek Company, in Chesterfield county, on the south side of James river, 12 miles from tide water, with which the mines are connected by a railroad. The mines may be considered accessible at all seasons of the year, as it is a rare occurrence in our climate that navigation is closed by ice.

"Very respectfully, your most obedient servant,

"JOHN I. WERTH,
"General Agent Creek Company.

"Commodore Bev. Kennon."

The exterior characters of this coal are generally as follows: The surfaces of deposition are not continuously developed in the fractures. In place of them, a great number of conchoidal surfaces having a resinous lustre alternate with spaces of a dull aspect. The main partings are at right angles to the horizontal surfaces. The cross partings appear not to be well defined either in position or extent. The main partings are in some specimens very conspicuously marked with patches of sulphuret of iron. The specific gravity of one specimen was 1.3163; that of another, 1.3228; giving the calculated weight of one cubic foot of coal in the mine, 82.48 pounds. The average actual weight in the condition of lumps, (in which state it was mainly found when ready for use,) was, by 41 trials, 46.496 pounds, or 0.5636 of the calculated weight in the solid state. The highest result was 51.62, and the lowest 40.62 pounds per cubic foot. In the merchantable state, fit for use in the steamers, one ton will require for stowage 48.176 cubic feet of space.

On analyzing the two specimens above mentioned, they were found to

contain the following materials:

Moisture	•	_	_		Specimen <i>a</i> . 1.074	Specimen <i>b.</i> 1.112
Sulphur	-	•	, <del>-</del>			2.894
Other volatile	matter	-	•	· <del></del>	` 28.666´	28.814
Ashes -	•	• 1	-	-	3.830	6.828
Fixed carbon	-	•	-	•	66.43	60.352
					100.	100.
Yelatile to fix	ed comb	ustible		1:2.317	1:1.903	

The coking of a was effected very slowly; that of b very rapidly. This, according to the result of a great number of trials, is sufficient to account for the difference in the relations of volatile to fixed combustible matter. On suddenly exposing a portion of this coal in powder to a bright red heat, the exterior becomes swollen and agglutinated, and at length hardened, before the interior has parted with all its gaseous matter. By continuing the heat, a quantity of confined gas is accumulated, sufficient to explode the agglutinated shell of the mass, which then develops a brilliant jet of flame.

The ashes from the analyses of specimen a are of a bright red; those of

b, of a dull brick-red color.

The weight of coal burned during four trials of evaporative power was 3,769.63 pounds, from which were obtained as residua 157.29 pounds of ashes, weighing 56 pounds per cubic foot; and of clinker 167.68 pounds, weighing 39.5 pounds per cubic foot; also, 20.75 pounds of soot from the flues, weighing 14.33 pounds per cubic foot.

The combustible matter in the ashes was 9.84 per cent. of their weight.

The total quantity of matter absolutely incombustible is, therefore, 323.12 pounds, or 8.5717 per cent.

Twenty-eight pounds of this coal, dried for three days in the steaming

apparatus, lost 0.406 pound, or 1.45 per cent.

Four trials of total volatile matter in two specimens of this coal afforded to Dr. King an average of 31.037 per cent. This result, combined with the two already given, presents an average of 31.118. From all these data, we may take the proximate constitution of this sample to be as follows, viz:

Moisture (from 28 pounds)	- 1.450
Other volatile matter (mean of four specimens)	- 29.678
Earthy matter (from 3,769.63 pounds)	- 8.572
Fixed carbon (calculated by difference) -	- 60.300
•	
	100.
Hence the volatile is to the fixed combustible	1:2.0318

It appears that both the specimens above analyzed gave proportions of earthy matter considerably below the practical average. The earthy matter of the clinker gained, instead of losing, by recalcination, to the amount of 13 per cent., and became of a dark reddish brown. The ashes were, after reincineration, a lighter red than the clinker, and the residue of the soot still lighter than that of the ashes.

A trial by the oxide of lead on specimen b, gave a reduction of metallic lead equal to 28.1 times the weight of raw coal employed; and as the moisture and ashes of that specimen were together equal to 7.94 per cent, the

lead to 1 of combus!ible was 30.523.

In ordinary smith's work, this coal was found to make a good hollow fire, with much flame; the heat from the latter very strong, but, of course, unavailable for the purposes of the work. In burning 60 pounds of it, the heating power developed was sufficient to put in nine links of a chain 1s inch in diameter. In an office grate the ignition was easy; the flame copious; many jets of gas of a high illuminating power were from time

to time thrown out, giving a brisk noisy fire from the hissing of these jets. To those who admire a bright blazing fire, it will be found eligible for parlor and other domestic grates.

The mean time for bringing the boiler into full action was 1.166 hour, and the average quantity of unburnt coke left on the grate was 10.53 pounds.

The coke is considerably intumescent, and coheres firmly; and these circumstances prove that, before employing it in a blast furnace for smelting iron, the process of coking will be requisite. This process should be performed slowly, and ought not, when conducted on open hearths, to be pushed to the extent of expelling the last portions of volatile matter, lest a part of the fixed carbon be also consumed.

This coal is judged to be well adapted to the production of illuminating gas, with the exception of possessing, in some portions at least, too large a

quantity of sulphur.

By a prompt application of heat, and a rapid development of the volatile constituents of the coal, a considerable portion of bi-carburetted hydrogen would be obtained, which is one of the principal objects of the gas manufacturer.

, U. 5	U. 10		opposite circumstances at the 3d trial.

[ 386 ] 362

#### General remarks on the preceding table of deductions, and on the experiments from which it is derived.

In all the experiments on the coal of the Creek Company, it will be observed that the grate remained of the same size, the circuit for the grace of the same length, and the chimney of the same height. The weight of coal burned at each experiment was also nearly the same. The period of

steady action varied from 4.75 to 6.25 hours.

The rate of combustion appears to have been considerably more rapid on the first than on any of the subsequentials, being 9.848 pounds per square foot of grate surface per hour, while the average for the other three days was but 8.177 pounds. The proportion of the total waste on the several days of trial varied but little. It was least when the rate of combustion was greatest—that is, on the first trial. This uniformity in the earthy residue shows that the sample had been so prepared for use as to exhibit a nearly equal purity throughout; very different from what happened in several other samples sent for these experiments.

It appears from the 18th line of the table of deductions, that, with the exception of the last trial, nearly the same quantity of water was supplied on each morning after terminating an experiment, in order to restore the level of water in the boiler to correspond to the existing temperature.

The rate of evaporation was very different on the different trials: 18.98 cubic feet of water were evaporated per hour on the first, and only 10.28 on the third. The average rate for four days was 14.885, which is between the free-burning bituminous coals and the artificial cokes already exhibited in connexion with the synoptical table of the free-burning class. The evaporative efficiency of the pound of coal given on the first trial (line 41) is materially above that in either of the others, and leads to the suspicion that the brisk action of the fire may have caused some water to escape on that day mechanically mixed with the steam. It was on that occasion found necessary to allow the steam to escape at both valves, in order to equalize the pressure, and prevent too much local ebullition by the current of steam flowing towards a single point of exit.

The two trials with the air plate open have evidently given results (as seen in line 43) which considerably surpass those obtained with the plate closed. This appears, in fact, to be the principal circumstance which caused a marked difference in the effect of this coal on the separate days of trial.

The tables of experiments show that the products of combustion were analyzed either wholly or partially on every day during the combustion of this sample. On the first day were made three; on the second, third, and fourth, each, two analyses. One point attempted to be ascertained by these trials, was the relative proportion of the principal products when, in the one case, smoke was flowing copiously from the chimney, and, in the other, when it discharged only invisible gases. It appeared, as a general result, that carbonic acid was in greatest abundance while smoke came most copiously from the flue, and that aqueous vapor was not then relative in so great quantity as at a subsequent period, when the smoke had disappeared.

#### No. 5.

Bituminous coal from the Clover Hilt mines, on the Appomattox river, Virginia.

The following letter states the origin of this sample, and gives other requisite information:

"Petersburg, June 19, 1842.

"Dear Sir: In consequence of the desire expressed by the Board of Navy Commissioners to be furnished with specimens of the different American coals, I have taken the liberty to order to be sent to the navy yard at Washington five hogsheads, containing a little upwards of two tons of coal, from the Clover Hill mines. This I hope the Board will do me the favor to receive, and submit to such tests and analyses as, in their opinion, may be calculated to prove its adaptation to steam purposes.

"The Clover Hill mines are situated on the Appomattox river, about twenty miles above the town of Petersburg, State of Virginia. The present shipping point for the coal is Petersburg, or City Point; and it can be delivered more cheaply or expeditiously at Norfolk than any other town or city on the Atlantic seaboard; but it may be shipped to any other seaport town, though at greater cost, as the location of its shipping point shows.

"As may be seen by examination of the specimen sent, from the square fracture and hard grain of this coal, it may be raised and transported in a lumpy state. The specimen sent was extracted from the mine about the 15th day of May last, and from that time till within a few days has been

exposed to the sun and weather.

"The specimen was taken from a cargo recently shipped to the navy yard at Gosport, in fulfilment of a contract made by the Clover Hill Company to furnish 800 tons of coal at that point for the use of the Government. I would respectfully suggest to the Board the propriety of seeking from the commandant of the Gosport station information in relation to the quality and size of the Clover Hill coal delivered there, as compared with coal delivered there by other contractors. It must be more satisfactory to be informed of the character and quality of coal, as well in mass as in specimens; for all mines will produce specimens superior to the general richness of the vein.

"If the Board be pleased with the coal, and desire a supply beyond the present contract, the Clover Hill Company are prepared to extend the contract to 2,000 or 3,000 tons, to be shipped during the summer or the next

winter, for the same price per ton as the contract already made.

"I have not thought fit to trouble the Board with a particular description of the Clover Hill mines, or to enter into details in regard to the thickness and extent of the vein, the facilities of transportation, &c., because not informed that such information was desired. But this, or any other information I have on the subject of coal in this section of the country, will be cheerfully furnished them at any time they may indicate a wish to receive it. I am pleased to see that the Navy Board have determined to seek information in regard to the adaptation of different coals to uses of generating steam. It is a subject of growing interest and importance; and the plan adopted to get information by an actual test of the different varieties, is

probably the best for both the miner and the Government that could have been adopted.

"Very respectfully, your obedient servant,

"JAMES H. COX,
"President of Clover Hill Company."

This coal differs considerably in aspect from any of the Virginia coals hitherto described. The color is dull black, and the surface is not unfrequently coated with carbonate of lime in scales of considerable thickness. The main partings are inclined in an angle of about 85° to the surfaces of

stre is mostly glimmering or resinous. The scales of e marked with specks of oxide of iron. The lumps, eighteen months, tend to disintegrate. The surfaces t, in some cases, the conchoidal fractures already nother samples from the same coal field.

ity of one specimen (a) of this coal was found to be 1.2823, and that of another (b) 1.2887; from which the weight per cubic

foot of the solid coal is calculated to be 80.355 pounds.

On weighing in the charge box, mostly in the state of lumps, all the coal burned at four trials, the result was 45.485 pounds per cubic foot; the highest number found in any one trial being 53.5, and the lowest 40.875. The average weight thus obtained is 0.566 of the calculated weight derived from the specific gravity.

The space for stowing 1 ton is 49.247 cubic feet.

The moisture expelled in analyzing specimen a was 1.409, and in b 1.277 per cent.

Twenty-eight pounds of the coal, in its average state, exposed for four

days in the steam drying apparatus, lost 6 ounces, or 1.339 per cent.

Specimen b gave of sulphur 0.5139 per cent. The volatile matter, excepting moisture, in a was 31.791; and, excepting moisture and sulphur, in b it was 28.409.

Of ashes, 87.12 grains of a gave 5.46 grains, or 6.267 per cent.; 303.07 grains of b gave 13.26 grains, or 4.3752 per cent.

From these data, we have-

,			Specimen a.	Specimen b.
Of moisture -	-	-	1.409	1.277
Of sulphur -	-	-	(not tried)	0.514
Of other volatile matter	•	-	31.791	28.409
Of earthy impurities	-	-	6.267	4.375
Of fixed carbon -	-	•	60.533	65.425
			100.	100,

The volatile to the fixed combustible 1:1.904 1:2.268

Two specimens, examined by Doctor King, gave, respectively, 31.25 and 37.50 per cent. of volatile matter, including moisture; and, as the two above given afforded the numbers 33.2 and 30.2 for the same ingredients, it may probably be safe to assume the mean of these four numbers, or 33.037, as the total volatile matter of this coal on a large scale, including hygrometric moisture. From this deducting 1.339, the moisture found in the steaming apparatus, we have 31.698 as the per centage of volatile combustible.

During four trials of evaporative power, there were burned 3,775.1 pounds of this sample; and the weight of ashes was 246.655 pounds, of clinker 149 pounds, and of soot 42 pounds. The ashes weighed 53.81 pounds per cubic foot, and lost by reincineration 14.93 per cent. The clinker weighed 44.62 pounds per cubic foot; lost nothing by calcination; but, on the contrary, gained very nearly 1 per cent. by peroxidizing the iron, which was previously partly in the state of magnetic oxide. The soot weighed 9.2 pounds per cubic foot, and lost 43.67 per cent. of its weight by incineration.

After making these deductions for combustible ingredients in the several residua, there were left 382.49 pounds of matter absolutely incombustible, or 10.132 per cent. From this analysis of the whole sample, we have—

Moisture	•	•	-	-		-	1.339
Volatile matte	r othe	er than r	noisture	•	•	' •	31.698
Ashes -	-	- '	•	•	•	•	10.132
Fixed carbon	•	-	•	-	•	-	56.831
							100.

This gives the relation of the volatile to the fixed combustible matter as 1:1.7929.

Oxide of lead reduced by specimen b gave 26.962 times its weight in metallic lead. Deducting ashes and moisture, this gives of lead to 1 of combustible matter 28.527.

On specimen b an experiment was made by the organic method of analysis.

For this purpose, 6.05 grains of the coal, perfectly dried, were treated with all the usual precautions with the scale oxide of copper. As the raw coal had 1.277 per cent. of moisture, and 4.3752 per cent. of ashes, the per centage of dry coal, which is composed of combustible ingredients, is 100—4.4318=95.5682; which shows that in 6.05 grains of dry coal there were 5.7818 grains of combustible materials.

The water collected in the chlo	ride tube, and su	lphuric acid		
bulb, weighed	•		<b>2.5</b> 8	grs.
The carbonic acid in the three to	bes for its recepti	on	17.68	
Hence, the hydrogen is 0.2866				
and the carbon 4.8217	$=\frac{6}{23}$ of the car	bonic acid.)		

The sum of these == 5.1083, deducted from 5.7818, leaves for oxygen and azote 0.6735.

Hence, the composition of 100 parts of the combustible matter of the dry coal is—

Oxygen and az	ote	•	. •	•	-	•	11.649
Hydrogen	•	~	~	-	•	•	4.958
Carbon	•	-	•	-	•	•	83.393

As the volatile matter, other than moisture, in 100 of the raw coal, was found, by previous experiment, to be 28.923 per cent., we may, from the foregoing analysis, deduce the weight of carbon which that volatile matter contained.

Thus, as the	moistu	re is	•	•	•	•	1.277	per cent.
Ashes -	-	•	•	•	•	•	4.375	- CC.
Trime I and ma	1-4:1	<b>L</b> 4!	Ca (Ca	rbon	•	•	78.680	66
Fixed and vo	nathe c	ompusii	ole $\langle H \rangle$	ydrogen	•	` •	4.677	Œ
(94. <b>34</b> 8) c	ompose	a oi	(0)	rygen at	nd azote	-	10.991	66
	•				è	1	^	•

the sum of the last two, 15.668, subtracted from 28.923, leaves for carbon, in the volctile matter, 12.055

in the volatile matter, 13.255.

Deducting the amount of hydrogen equivalent to saturate the oxygen in the coal, we have left 3.303 parts; and admitting the heating power of this to be 62,535, according to the result of Dulong's researches, we obtained 62535 × 0.03303=2065.5=the weight of water heated one degree Fahrenheit by the burning of the hydrogen in one pound of this coal. By assuming the heating power of carbon to be 12.906, according to the same authority, we have 12906 × 78.68=10154.5=the heating power from the carbon in one pound of coal. The sum of these two numbers is 12.220=the number of pounds of water heated 1° by the combustible ingredients, omitting the sulphur. This number, divided by 1030°, the latent heat of the vapor of water, gives 11.864 pounds of water converted into steam from 212°, by the combustion of one pound of this coal.

Comparing the above result with the practical heating power, as given in the table of deductions, we have a wide difference. The highest amount of water from 212° to 1 of coal, was only 8.0468. The apparatus for drawing gas from the chimney had not been arranged at the time this sample was burned; and I cannot, therefore, offer any direct observations to test the products of its combustion, from which to derive its heating power, such as are contained in a subsequent part of the report, upon various other sam-

ples of coal.

But we may deduce this from another source.

The table of deductions, following those of experiments on this coal, furnishes the highest amount of water evaporated from 212° to 1 of com-

bustible matter in the coal, 9.1513, and the average 8.5885.

In burning the Tippecanoe coal, (which is in all respects a perfect counterpart of the Clover Hill, the two pits being, I understand, in close proximity and on the same bed,) the gases of the chimney were analyzed, and the heat expended on all the principal absorbents is calculated. The evaporative power of 1 of coal in that case, as derived from the steam it expelled from the boiler, was 8.408; and the total power expended on all the absorbents is 10.29. Hence, of the total evaporating power measured, there was employed on the boiler 81.504 per cent.

The water evaporated by 1 of combustible matter on the same day was 9.2932; and the total evaporative power to 1 of combustible must, there-

fore, have been 11.402.

Taking 81.504 per cent. as the proportion of heat expended on the boiler in the case of Clover Hill coal, the total maximum evaporative power of 1 of combustible was 9.1513+0.81504=11.228; and the average is 3.5885+0.81504=10.537. To compare this with the result of the above analysis, we have the carbon in one of combustible 0.83393: and this multiplied by 12906, gives 10745 as the heating power; and the steam evaporating power is 10745+1030=10.445. Hence, the carbon alone appears to be adequate to produce the whole average evaporative effect observed. The excess of hydrogen was 0.03502 of the combustible matter, and 0.03502 ×

62535=2190=the computed heating power of the hydrogen, of which the

equivalent in evaporative power is 2.126.

When tried in the smith shops, the workmen complained that this coal made a large amount of cinder; would not form a good follow ire of any considerable durability; and that it corroded, or, as one expressed it, "ate up" the iron.

In burning, it falls into small lumps, which, under the steam loiler, occasioned a large portion to pass through the grate, and is the snith's fire prevented forming a durable arch. In office and parloi grates, the same

cause produces a strong tendency to waste.

For the manufacture of iron, it will require coking and where this operation is performed on large quantities, the agglutinaton may robably be sufficient to constitute a suitable fuel for that purpose.

The average time required to bring the boiler to steady action, while

burning this coal, was 1.933 hour.

The weight of coke left unburnt 11.512 pounds.

It will be remarked that it yields a very large amount of soot. The accumulation of it in the interior flues of the boiler was such as todiminish their opening nearly one-half; and in the outside flues, the surface of the boiler there exposed was covered from an inch to an inch and half in thickness, in the course of four trials.

#### No. 6.

Bituminous coal from the Chesterfield Mining Company, Chesterfield county, Va.

The following statement accompanied this sample:

"WASHINGTON, June 29, 1842.

"GENTLEMEN: On the 24th instant, I forwarded to the navy yard at Washington five hogsheads of bituminous coal, for the purposes stated in the advertisement.

"I have the honor to inform you that this coal has been mined within the last month, and is from the pits of the Chesterfield Mining Company, situate in Chesterfield county, within twelve miles of Richmond, Va., and formerly known as the "Black Heath pits," and which have been lately purchased by English capitalists, whose general agent and manager I am.

"The coal could be delivered any where in the United States.

"I have the honor to be, gentlemen, with great respect, your obedient humble servant,

"R. I. D. GIFFORD.

"To the Hon. the Board of Navy Commissioners, Washington."

In external characters, this coal is much nearer to the Midlothian than to the Clover Hill coal, last described. It was received generally in lumps of considerable size, which will, in part, account for its lowness in weight per cubic foot. Efflorescent sulphate of iron is of frequent occurrence; and carbonate and sulphate of lime are also observable at the partings. Conchoidal fractures and a resinous lustre are conspicuous along the horizontal partings. The coal appears to have been mined with a degree of care not always found in samples from the same coal region. Few or no fragments of slate were noticed. It was observed to give but little waste coal, or coke, passing through the grate, and to produce a long dense flame, without decrepitation. The powder is of a dark clove-brown color, and its streak on white earthen ware is nearly of the same tint.

The specific gravity of one specimen (a) was 1.2938, and that of another (b) 1.2839, giving the calculated weight per cubic foot 80.565 pounds.

By 43 trials in the charge box, the average weight per cubic foot was found to be 45.549 pounds, or 0.5653 of the calculated weight—the maximum being 54.375, and the minimum 40. From this average, the space required per ton is 49.178 cubic feet.

The moisture in specimen a was 1.094 per cent.; in specimen b, 1.197. Twenty-eight pounds in the steam drying apparatus lost, in two days, 0.531

pound, or 1.896 per cent.

The sulphur in a was 1.957 per cent.; that in b not ascertained.

The volatile matter in a, other than moisture and sulphur, was 31.739;

that in b, other than moisture, but including sulphur, 27.353.

The ashes of a, by a mean of four incinerations, were 4.72 per cent.; their color, when hot, a dark blackish gray; when cold, reddish gray. Those of b, by the same number of incinerations, 6.13 per cent.; grayish white when hot, becoming salmon color on cooling.

The following, therefore, exhibits the composition of these two speci-

mens, viz:

Moisture	•	•	•	•	•	′ 8	pecimen <i>a.</i> 1.094	Specimen b. 1.197
Sulphur	•		-	-	•	•	1.957	(not tried.)
Other volatile	matter	-	•	-		-	31.789	27.353
Ashes -	• .	•	•	•	•	•	4.720	6.130
Fixed carbon	•	•	• '	•	•	•	<b>60.49</b> 0	65.320
							100.	100.
7	Volatile	to fixed	combus	tible	•	•	1:1.795	1:2.3958

To compare the above results with that derived from the furnace, which exhibits the practical determination of the waste matter of the coal, it may be stated, that in burning 3,876 pounds of this coal, there were obtained 185.5 pounds of ashes, including 1.644 pound of ashes of wood, and that their weight per cubic foot was 47.29 pounds. They lost by reincineration 18.744 per cent., and became of a light ochrey-red color. The clinker, which weighed 166.75 pounds, was of moderate density, weighed 37.62 pounds per cubic foot; having a brown color on the fused surfaces, and black within; its masses large, evidently prone to spread out into sheets, with some light-colored patches diffused through it. The clinker gained in weight nearly one per cent. by calcination, leaving a dark-brown residue. The soot collected (26.25 pounds) weighed 22.7 pounds per cubic foot, and lost 28.67 per cent. by incineration, leaving a reddish-gray ash.

Hence, after the above deductions, and subtracting the ashes of wood,

we have left 334.665 pounds, or 8.6343 per cent., of absolute waste.

The total volatile matter, including moisture, in two specimens tried by Dr. King, was 33.25 and 33.70, which, with the two above presented, afford a mean of 32.572. From this, deducting the moisture (1.896) obtained in the large apparatus, the remainder (30.676) may be assumed as the average of volatile combustible. Hence, in 100 parts of the raw coal, we have of—

Moisture -	•	•	•	•	•	•	•	1.896
Volatile combustible	-	•	•	•	•	•	•	30.676
Earthy matter	•	-	•	•	-	-	•	8.634
Unvolatilizable carbon	-	•	-	•	•	•	-	58.794
							,	100.
There also also also	1-A	1. !. 4.	AL - C	1	-49-1-			1.0166

From the above, the volatile is to the fixed combustible as - 1:1.9166 A trial of 20 grains of specimen a, by the oxide of lead, resulted in pro-

A trial of 20 grains of specimen a, by the oxide of lead, resulted in producing 516.68 grains, or 25.784 times its weight of metallic lead; and this, after deducting moisture and ashes, is 27.376 of lead to 1 of combustible matter. Sixty pounds were found in the chain shop sufficient to make 9 links of 1%-inch chain.

The flame is large, and the fire very hot. No deleterious effect was produced on the iroh. At the anchor shop, when an equal quantity was used, it produced a good hollow fire, yielded but little cinder, and gave a good welding heat, without injuring the iron. Its proportion of volatile matter is such as to adapt it to the purpose of manufacturing illuminating gas. The long and brilliant flame which it produces renders the fire of a grate exceedingly cheerful.

When thrown into the furnace already in brisk action, it produces almost instantly a copious flame, and yields a good coherent coke, of which

but little passes through the grate.

The average time required to bring the boiler to steady action was 1h. 10m., (1.166 hour,) and the average weight of coke left was 10.469 pounds.

The manufacture of iron from the ore could not be advantageously carried on with this coal, without the preliminary process of coking.

#### No. 7.

Bituminous coal of average size, sent by the Midlothian Coal Co, Va.

This sample, together with one in the state of lumps, is referred to in the following letter:

"RICHMOND, June 23, 1842.

"Sin: Above I hand you a bill of lading for ten hogsheads Midlothian coal—five being screened coal, and five average coal—designed for trial for the steam service. The average coal is about 8 per cent. heavier, and about 15 per cent. cheaper, than the screened coal; and consequently it is of importance to the Government if this description of coal shall be found suitable for the naval steam service, particularly as any quantity of that kind of coal can always be obtained.

"The Midlothian mines lie about thirteen miles west of Manchester, are connected with tide water just below Manchester by a railroad, where the coal is shipped in vessels carrying less and up to 7,000 bushels. This coal has been extracted from the mines during the present year, and can be shipped at any of our cities on the Atlantic coast, or points where schooners can navigate on the Mississippi and the Gulf of Mexico.

Most respectfully, yours, "A. S

"A. S. WOOLDRIDGE,

" President of the Midlothian Coal Mining Co.

"Com. Kennon, Comdt. of the Navy Yard, W. C."

This sample exhibits the main partings inclined to the surfaces of deposition in an angle of about 80° or 81°. The planes of both the main and cross partings are marked with scales of carbonate of lime.

In the course of eighteen months, specimens not exposed to any other moisture than that in the atmosphere of a dry apartment, have become almost entirely disintegrated by the efflorescence of the sulphuret into sulphate of iron. This circumstance abundantly indicates one of the impurities of the coal, and points to its probably becoming heated if exposed in large quantities to the influences of the air for any very protracted period.

The coal produces on a white ground a brown streak, and its powder is

also brown.

The specific gravity of two specimens (a and b) was found to be, respectively, 1.3006 and 1.2882, from which the calculated weight of one cubic foot is S0.895 pounds.

The weighing and measuring of forty-two charges, of which the least contained 46.25, and the greatest 58.125 pounds per cubic foot, resulted in establishing the average of the whole at 54.044 pounds, which is 0.668 of the above calculated weight. The space for stowing one ton is 41.448 cubic feet.

The analyses of the two specimens above referred to afforded the fol-, bwing results, viz:

					Specimen a.	Specimen b.
Moisture -	•	-	_	-	0.997	0.765
Sulphur -	•	•	•	-	(not examined)	0.057
Other volatile ma	tter	-	-	-	<b>3</b> 1.093	30.217
Earthy matter	-	-	•	<b>-</b> ,	4.800	4.375
Fixed carbon	-	•	•	-	63.110	64.585
					100.	100.
Volatile to fixed o	ombu	rtible	•	-	1:2.0297	1:2.133

The volatile matter, including moisture, in two specimens examined by Dr. King, was found to be 33.251 per cent.; which, combined with the above, give the mean for four specimens of 32.251 per cent. of products volatilizable at redness.

The moisture expelled by drying 28 pounds for two days was 11 ounces, or 2.455 per cent.

The combustion of 4,506.39 pounds of this coal yielded—

278.39 pounds of ashes, weighing 53.8 pounds per cubic foot.

402 pounds of clinker, " 37.50 " " 28 pounds of soot, " 19.06 " "

The ashes lost by reincineration 10.09, the clinker 0.968, and the soot 36.66 per cent. Making these reductions, and subtracting the ashes of wood consumed in raising steam, (2.36 pounds,) the remainder is 664.105

pounds, or 14.737 per cent. of the coal actually consumed.

The clinker is dark brown, or black, with portions of lighter colored shaly matter disseminated through it. The masses are large and porous. This circumstance, together with the minute subdivision in which the sample was found, caused much clogging of the grate; demanded frequent use of the slice bar to keep it moderately free; and required the contents of the ash pit to be several times returned to the grate, to prevent the loss of much small coke and coal.

When completely calcined, the clinker becomes reddish brown, or dork red gray. After reincineration, the ashes are of a deeper red than the clinker; and the residue of the soot is of a dull brick-red that, while the ashes from analysis are of a blackish-gray color.

The experiments on the entire sample may be represented as giving the

following composition of this coal:

Moisture -	-	•	•	-	-	•	-	2.455
Other volatile matter	-	•	•	-	•	•	-	29.796
Earthy matter	-	•	•	-	1 •	-	•	14.737
Fixed carbon -		•	•	•	•	-	•	53.013
•								
•							•	100.

Hence the volatile to the fixed combustible is 1:1.78.

With oxide of lead, the reductive power of specimen b was found to be 27.344, which, after deducting earthy matter and moisture, gives for 1 of combustible matter 29.027.

The action of this sample in smith work was proved only in the anchor shop, where it was used in heating large bars about three inches square. It worked well, forming a good hollow fire, produced a light coke, and gave

a large amount of cinder.

In an office grate it exhibited, when thrown on a mass of ignited coke, an immediate development of brilliant flame; and though, by the rapid absorption of caloric by the gas and vapors produced, the heat of the fire was necessarily in some degree checked, the flame did not wholly cease, as often happens, while the vapors of water and tar were passing off. When undergoing the partial fusion which attends the rapid evolution of gas and vapor, it sends out jets of white flame of great brilliancy. This, together with the amount of its gaseous products, marks its adaptation to the purposes of producing illuminating gas.

The average length of time required to bring the boiler into steady action was 1.516 hour; and the weight of coke left unburnt on the grate was,

on an average of five trials, 6.442 pounds.

#### Remarks on the preceding table of deductions.

The third and fourth trials were made with the lower damper open 12 inches; and the former with air plate open, the latter with it shut. With the former arrangement, the gases reached the chimney at an average temperature of 448°, and with the latter at 439°. The higher temperature was accompanied by a range of the syphon gauge slightly superior to what prevailed during the trial with lower temperature. The pound of combustible matter produced more steam with the closed than with the open air plate; and the evaporation with the closed plate also exceeded that with it

open, in the proportion of 11.96 to 10.4, as proved in line 21.

For the whole time of burning this coal, the chimney was but 41 feet in height, and the comparison of its average rate of evaporating ought to be made with that of other coals burned under similar circumstances. average of the five trials is 10.09 cubic feet per hour; that of Karthaus was 12.48; that of Cambria county, Pennsylvania, 12.46. Both the latter coals were in the average state as to size of lumps. It appears that the total waste of this average Midlothian coal, in ashes and clinker from the grate, was 14.827 per cent. By table CXVI, it appears that the Midlothian coal from the 900 feet shaft left, on an average, 10.702 per cent. of similar waste. In a subsequent table, (CXLVII,) it will appear that the screened coal from the same company's mine, called new shaft, left 10.258; and by table CLIII, the Midlothian "screened" coal will be seen to have afforded 10.34 per cent. of waste. All these latter samples appear to have been mined with care, or at least properly separated from slate and dirt; and their very near conformity with each other indicates that a reliance can be placed on this coal, when thus mined and prepared for market, to afford about \$9.5 per cent. of its weight in combustible matter. This coal was found to pass in considerable quantities through the grate, requiring much attention to avoid excessive waste.

Where it is stated in the tables of experiments that the contents of the ash pit were thrown on the grate, (as generally happens near the foot of the column of "remarks,") it is not to be understood that all which had passed the grate during the day had remained in the ash pit till that time; on the contrary, the contents of the ash pit were frequently returned to the grate throughout the day. The operation generally noted was that which mark-

ed the final disposition of the fuel for the closing of the experiment. This mode of disposing of the contents of the ash pit makes the results in regard both to evaporative power, and to proportion of waste, considerably more favorable to every sample than they could be expected to appear according to the usual mode of conducting combustion. The tendency of the coal or its coke to pass through the grate is generally noted, and its liability to loss from this cause may be inferred. In practice on board of steamers, something might, no doubt, be saved by a judicious application of the fallen portions of fuel, which I believe are now generally condemned to go overboard with the cinders. It has been stated that instances have occurred in which nearly 50 per cent. as much weight of matter was thrown out from the ash pit as had been taken on board in the state of coal. If any approach to such a result were really obtained, it argues either the use of a coal far inferior to any which has come under notice in these experiments, or an exceedingly injudicious and wasteful mode of applying it. Instances will be found, in different parts of this series of trials, in which the liability of bituminous coals to fall into fine coke increases this liability to waste beyond what is due to the finer parts of the coal.

#### No. 8.

Bituminous coal from the Tippecanoe pits, near Petersburg, Virginia.

The following letter accompanied this sample:

"PETERSBURG, June 17, 1343.

"Sirs: Herewith we enclose your bill of lading for six hogsheads bituminous coal, from the Tippecanoe pits, and certificate; which, if deficient in form, or otherwise objectionable, you will please let us know, that we may remedy the deficiency.

"The coal sent was taken from the pits this month, and can be delivered either in Boston, New York, Baltimore, Norfolk, or Charleston; though

Norfolk would be the most convenient point of delivery.

"Respectfully, your obedient servants,

"J. C. & J. D. OSBORNE & CO.,
"Agents Tippecanoe Coal Company."

In many respects, this sample resembles that from the Clover Hill mines, which has already been described. It parts, however, more readily along the surfaces of deposition, being evidently aided by the great quantity of efflorescent sulphate of iron, which shows itself in those seams. The inclinations of the main partings to those surfaces, in several specimens, were measured, and found to be 83 and 97 degrees. Specimens kept dry for 18 months are already disintegrating. Yellow sulphuret of iron is abundantly distributed over some surfaces of recent fractures. When received, and when placed on the grate, this sample was almost wholly in lumps of considerable size; one or two charges only of fine coal were taken from each hogshead. This will, in part, explain the difference between its weight per cubic foot, as ascertained by actual weighing, and that of several samples of "average" coal from the Virginia coal district.

The powder of this coal is of nearly as light a brown as that of cannel

coal, and approaches that of asphalt; its streak is also brown.

The specific gravity of one specimen (a) was 1.235; that of another (b) 1.4225. The former giving for the weight of a cubic foot 79.37, and the latter 88.91 pounds; of which the mean is 84.14. This very considerable difference in specific gravity was doubtless due to the much greater quantity of earthy matter in b than in a; but the mean weight per cubic foot may probably not differ far from the actual mean weight of solid coal in the mine, since the average amount of earthy matter, determined in the furnace operations, is not far from the mean amount of the two specimens.

By an average of fifty-five trials in the charge box, the weight per cubic foot (mostly in the state of lumps) was found to be 45.1 pounds, or 0.536 of the above calculated weight. This shows that 49.668 cubic feet of space will be required to stow one ton. The greatest difference between any two charges was found during the first day's trial; in which, the least weight per tubic foot was 41, and the greatest 52.75 pounds.

The moisture in specimen a was 1.235 per cent., and that in b 1.395.

The drying of 28 pounds in the steaming apparatus for four days occa-

sioned a loss of 1.841 per cent.

The sulphur found in a was 0.3775 per cent. The volatile matter, other than moisture and sulphur, in a, was, by slow coking, 29.218; and by

rapid coking, 33.378 per cent. By a mean of two trials on b, it gave, hesides moisture, 32.39 per cent. of volatile matter.

Four incinerations of a yielded an average of 2.92 per cent., and eight

of b gave 14.804 per cent. of ashes.

These two specimens may, therefore, be stated to consist of the follow-

ing proximate ingredients, viz:

_			,	•	Specimen a.	Specimen b.
Moisture `	•	•	•	•	1.235	1.395
Sulphur -		•	•	-	0.377	(not tried.)
Volatile combu	stible,	by rapid	coking	•	33.378	32.390
Earthy matter	•	•	-	-	2.920	14.804
Fixed carbon	•	•	÷	-	62.090	51.411
					100.	100.
Volatile to fi	xed co	mbustibl	le	•	1:1.860	1:1.586

Two specimens examined by Dr. King gave the mean amount of volatile matter, including moisture, 37.625 per cent.; and this, combined with the mean of the two above presented, viz: 34.387, gives as the average of

four specimens 36.006.

During the experiments on evaporation, there were consumed, at five trials, 4,904.75 pounds of coal; and this afforded of ashes, including those of wood, 279.125 pounds, weighing 57.44 pounds per cubic foot; of clinker, 200.5 pounds, weighing 43.37 pounds per cubic foot; and 44 pounds of soot, weighing only 5.54 pounds per cubic foot.

The ashes lost by reincineration 8.48, the clinker 3.915, and the soot 64.74 per cent. of weight. By reducing the above numbers in these pro-

portions, we have—

```
Of absolutely incombustible matter in the ashes - 255.45 pounds.

clinker - 192.65 "
soot - 15.51 "

From which deduct ashes of 1,246.25 pounds of wood = 3.826 "

And we have of incombustible matter of the coal alone 459.784 "
```

Which is 9.374 per cent. of the coal consumed.

Hence it appears that the mean proportion of earthy matter of the two spectmens above analyzed, viz:  $\frac{2.92+14.804}{2}$  =8.862 per cent., is 0.512 less than the average of that of the whole sample.

From these determinations on the large scale, we have the composition

of the coal as follows:

Moisture, by drying 28 pounds Other volatile matter, mean from 4 spe Earthy matter, from 4,904.75 pounds Fixed carbon, computed by difference	•	-	1.841 34.165 9.374 54.620	•	« «	
	•		100.			

The volatile is to the fixed combustible as 1:1.5987

The clinker of this coal is, in all respects, similar to that of the Clover Hill sample. By reference to a tabular comparison of residua, in a subsequent part of this report, (table CXC,) it will be seen that while the last-mentioned coal gave 3.86 per cent. of its weight in clinker, the Tippecanoe gave 4.03—a difference which may easily have arisen from differences in the rates of combustion, which in the latter was 108 pounds, and in the former only 90 pounds per hour. The gauge which indicated the draught in the chimney will be seen, on inspecting the table of deductions, to have marked a difference corresponding to this difference of rates; and the intensity of ignition, being in some degree proportionate to the rate of combustion, will account for a larger amount of clinker in one case than in another. The final residue of the clinker, after calcination, is of a bright red color; that from reincinerating the ashes is slightly lighter; that from the soot still a shade lighter; and the ashes from analysis vary from an ochrey yellow to a bright red.

Treated with oxide of lead, 20 grains of the above described specimen (a) yielded 559.16 grains, or 27.958 times its weight of metallic lead; and this, after deducting moisture and earthy matter, is 29.17 to 1 of combus-

tible matter of the specimen.

The soot contained 13.904 per cent. of volatile matter, and 50.84 of fixed carbon.

In the smith's fire this coal was found well suited for the small work in hand at the time it was tried. It produced but a moderate quantity of cinder. The coke becomes very hard, which was judged to favor the formation and continuance of a large hollow fire. It heats well, without appa-

rently injuring the iron.

In the chain shop, where it was used in making the links of a small chain, the workman complained that the welding was sometimes interfered with by the sulphur of the coal. The coke appeared not inclined to agglutinate strongly; but in that case, as a hollow fire was not required, no attempt was made to produce one. The hardness of the coke was rather objectionable than otherwise.

In an office grate, it was found to give a brisk, highly luminous flame,

resembling that of the Midlothian coal.

For the manufacture of illuminating gas, it is perhaps equal to any other Virginia coal. The amount of its volatile ingredients is greater than that of Nova Scotia coals. Its distillation will, no doubt, give rise to a considerable quantity of ammoniacal liquor, and probably of carbonic acid, from the earthy carbonates distributed through the seams. Sulphuretted hydrogen will also be found among its gaseous products.

It could not be employed in the smelting of iron from the ore, without

previous coking.

In the furnace of the steam boiler, it was observed to ignite promptly, burn freely, with a large dense red flame, and to agglutinate while coking,

so as to allow but a moderate quantity to pass through the grate.

The average time required by this coal to bring the boiler into steady action was 1,333 hour; and the weight of coke lest unburnt, after the fire had become extinct, was 11.25 pounds. In this last circumstance, it corresponds very nearly with the Creek Company's coal, the Clover Hill, and the Chesterfield Mining Company's samples.

#### No. 9.

# Bituminous screened coal from the mines of the Midlothian Coal Company's "new shaft," Virginia.

For information relative to the origin of this coal, I relied on the markings of the casks which contained it, and which purported that it came from a "new shuft" in the company's works, from 700 to 800 feet deep. It was received and used in the lump form, which it retained with considerable force. Its fresh fractures present a shining black resinous, scarcely conchoidal aspect, with distinct lines of the laminæ of deposition. It is mostly free from incrustations of earthy matter, but occasionally presents some shaly or pyritous portions.

'The powder is of a light brown, indicating a pretty high degree of bitu-

minousness; and its streak is nearly of the same color.

The specific gravity of two specimens (a and b) was found to be 1.3495 and 1.3006, respectively; the mean of which affords by calculation the

weight of 1 cubic foot of the coal in the solid state=82.43 pounds.

By thirty-one trials in the charge box, the mean weight per cubic foot was ascertained to be 47.899 pounds—the lowest result being 42.75, and the highest 54.125. Hence the actual is to the calculated weight as 0.5811 to 1.

The space required for the stowage of one gross ton is 46.769 cubic feet. In the analysis of specimen a, the moisture was found to be 0.74 per cent., and that of b 0.914 per cent. In the steam drying apparatus, 28 pounds lost in three days only 3 ounces, or 0.6696 per cent.

The sulphur in b was 2.282 per cent.

Of volatile matter, other than moisture, a had 34.72, and b 31.556 per cent.

The coking took place with the emission of a beautiful bright flame. This indicated a large proportion of olefiant gas, and the absence of carbonic acid, or other incombustible gaseous matter. Two specimens tried by Dr. King gave a mean of 35.75 per cent. of volatile matter, including moisture.

The incineration of a produced 9.549, and that of b 5.48 per cent. of the raw coal. Hence, the composition of the two may be thus represented:

					Specimen a.	Specimen &
Moisture	-	•	•	•	0.740	0.914
Sulphur	-	140	•	•	(not tried.)	2.232
Volatile combu	ıstible	-	•	-	34.720	29.274
Earthy matter	•	•	•	-	9.549	5.480
Fixed carbon	•	•	•	•	54.991	<b>62.050</b>
			•	•	100.	100.
Volatile	to fix	ed com	-	1:1.584	1:1.966	

The quantity of coal burned during the three trials of evaporative effect was 2,918.5 pounds.

#### The waste matter withdrawn consisted of-

Ashes, includ	ing 1.93	32 poun	d of wo	od ashes	-	175.25	pounds.
Clinker	•	• ,	•	•	•	126.25	• 66
Soot -	- •	•	•	-	-	14.00	46
The ashes los	t by rei	ncinera	tion ·	-	-	16.18	per cent.
The clinker	•	•	•	•	•	0.00	- "
The sout	•	•	•	•	•	56.75	66,

Reducing the ashes and soot in these proportions, and deducting the wood ashes, we have left 277.4—1.932—275.473 pounds of absolutely incombustible matter, or 9.44 per cent. of the coal consumed. The trials in the large way show this coal to consist of—

Moisture, from 28 pounds - Other volatile matter, from four specimens	-	-	0.6696 33.4904
Earthy residuum, from 2,918.5 pounds Fixed carbon, by difference -	•	•	9.4400 56.4000
Place carbon, by difference -	-	<b>-</b>	100.

The volatile is, therefore, to the fixed combustible as 1:1.684.

The weight per cubic foot of the

```
Ashes, was - - - - 56.65 pounds.
Clinker - - - - 30.12 "
Soot - - - - 5.46 "
```

The clinker is brown on the outside; but on the fractured surfaces black, very compact, and heavy; in sheets of considerable extent, manifestly very fusible, and tending to adhere to the grate. The highly ferruginous character which it presents, is in accordance with the large amount of sulphur which was detected in one of the specimens above analyzed.

The shaly portions embraced in the vitrified clinker are nearly obscured by the fusible coating which encloses them.

A portion of the specimen b, above analyzed, was subjected to treatment with the oxide of copper: 4.57 grains were thoroughly dried; and the result of their treatment, with all the precautions required by the experi-

ment, was of water 2.23, and carbonic acid 14.82 grains.

The earthy matter of the raw coal having been determined, as also the moisture, by previous experiments already detailed, it is easy to calculate the weight of earthy matter in 4.57 grains of dried coal to be 0.25274 grain, which leaves of combustible matter 4.31726 grains; the hydrogen, by analysis, is 0.24777, the carbon 4.04182 grains; leaving for oxygen and azote only 0.02767, or the relation of these three to their sum is—

```
Carbon - \frac{4.09189}{3.1726} = 93.6200 = 15.60 C. in atoms. Hydrogen - \frac{9.94777}{4.31726} = 5.7391 = 5.74 H. "Oxygen and azote - \frac{9.93767}{4.31726} = 0.6409 = 0.80 O. "
```

In the raw coal, this analysis enables me to state that the ingredients are —

Oxygen and azote Earthy matter -	•	•	-	-	•	0.600 5.480
Hydrogen -	-	-		•	•	5.972
Carbon	-	•		•	•	87,634
Moisture -	•	•		•	•	0.914

That the relative amounts of carbon and hydrogen were correctly determined in the preceding analysis, was rendered highly probable by the result of another trial, in which the apparatus became injured before the combustion was complete; but the ratio of the two products to each other was very nearly the same as in the preceding trial: The carbon was 1.2736 grain, against hydrogen 0.07222 grain. As the sum of the hydrogen and oxygen is 5.972 per cent., and that of sulphur 2.282, it is inferred that, in the volatile matter produced by the distillation of this coal, there will be found 29.274—5.972—23.302 per cent. of its carbon. If the heating power be calculated from the above analysis by the organic method, without taking account of the sulphur, and only deducting of the hydrogen so much as is equivalent to the oxygen present, we have the calorific power expressed by 14,596; \* 'or in pounds of water from 212°, for 1 of coal, 14.171. This is far above the actual result of experiment. The highest evaporative power, even when allowance was made for the heat expended on the products of combustion, as well as for that employed on the steam of the boiler, was but 10 1915. This will be evident from an inspection of the table of analyses of gases from the chimney. (See table CXCIV.)

A trial of specimen b by the oxide of lead gave 25.084 times its weight in metallic lead. Deducting earthy matter and moisture, this gives for 1 of combustible matter 26.797.

In both the chain and anchor shops, the action of this coal was entirely satisfactory. It was tried near the end of the season, and was pronounced by the workmen (now accustomed to observe carefully the action of each coal) to be one of the best, both for large and small fires, which they had tried.

The characters already detailed are sufficient to indicate its fitness for domestic purposes. It ignites rapidly, having required, on an average, only 0.906 hour to bring the boiler to steady action. It burns with a long, dense, deep-red flame—agglutinating when first thrown on the grate into

Thus the carbon is 0.87634 of the coal, (considering all that was collected in the potash tabe as carbonic acid;) and this multiplied by 12,906, (Dulong's result for the heating power of carbon,) we have 11,284 for the computed heating power of the carbon in the coal. This divided by 1,030 gives the steam generating power to 1 of coal—10.955. Deducting \( \frac{1}{2} \) of 0.600 (the oxygen) from 5.372, we get 5.297; and, multiplying by 62,535, (the heating power of hydrogen,) we obtain 3.312; and the sum of these is 14,596, as above. By deducting the moisture (0.6696 per cent.,) and the waste left in the third trial of this coal, (10.397 per cent.,) we have the remainder 88.933 per cent. of combustible matter, by which the total evaporative affect 10.1915 must have been produced. Hence 10.1915; 0.88933—11.460—the evaporative power of the unit of matter actually burned in that experiment. Again: as in the sample analyzed, the combustible part is 0.87634+0.05372+0.00600—0.93606, the carbon is 0.87634+0.93606—0.9362 of that combustible; and 0.9362×12906—12063, the heating power of the carbon in 1 of this combustible; and, finally, 12083:1030—11.731—its evaporative power.

a rather solid, moderately intumescent mass, requiring some effort to break it up. When thoroughly ignited, it still retains sufficient size to prevent much waste through the grate. The average weight of unburnt coke left on the grate after each trial was 17.083 pounds.

On the subject of the pressures maintained in the course of these experiments, I would remark, that in several instances it became necessary to increase the ordinary weights on the safety valves, to prevent foaming, and especially to equalize the discharge of steam from the two. This was done by small additions placed upon the principal weights, and which were varied from time to time, as the action of the boiler seemed to demand. When a strong west or northwest wind aided the draught, a larger portion of steam was permitted to escape at the back valve, and the front one was loaded. If, on the other hand, the gauge for draught indicated a deficiency, the front valve was relieved, and more steam allowed to pass into

the chimney.

In regard to the observations of temperature of steam in the boiler, it was found necessary frequently to attend to the thermometer inserted in it, lest, by the slow evaporation of mercury, which takes place at degrees below the boiling point of that metal, some portions should become lodged in the upper part of the tube. The vapor, being invisible, lodges for a time in so fine globules on the interior of the glass, as not to attract attention. On reversing the instrument, however, and gathering all the dispersed portions, the total length of the column may sometimes be found increased from 1 or 2 to 4 or 5 degrees. In some of the earlier experiments, it will be observed that the temperature of steam in the boiler ranged as low as 229, or even 228 degrees, while the average is from 230 to 231 degrees. It will be seen that, during the trials of this coal, the temperatures and pressures were maintained with tolerable uniformity throughout. This will appear from table CXLVII. The first thermometer had a range rather lower than that which was employed at a later period of the research. The error was from 11 to 2 degrees.

#### No. 10.

Bituminous screened coal, from the Midlothian Company's mines of Virginia.

Information relative to this sample is conveyed in the letter of Mr. Wooldridge, already copied, in connexion with the sample of average coal from the same mines.

It was generally in large lumps, appearing to have but little tendency to disintegrate. Its color is mostly deep black, but diversified by scales of carbonate of lime, which incrust the main and cross partings.

The conchoidal fracture, shining or resinous lustre, and the difficulty of procuring fractures of much extent following the surfaces of deposition, are

observable in this, as in other samples of Virginia coal.

The specific gravity of one specimen (a) was found to be 1.2906, that of another (b) 1.2763. The mean of these gives the calculated weight per cubic foot in the mine, 80.21 pounds. As the result of 46 trials, by measuring and weighing in the charge box, the least weight per cubic foot was 39.875; the greatest, 53.75; and the average 45.722 pounds, or exactly 57 per cent. of the weight derived from the specific gravity.

The space for stoying one ton is 48.992 cubic feet. The moisture in specimen a was 0.902, that in 6 0.888 per cent. In the larger operations in the steaming apparatus, 28 pounds lost 0.5 pound in two days' drying,

or 1.785 per cent.

The sulphur in specimen a was 0.2025 per cent.

The total volatile matter in a, by two trials, was 40.117; in b, by one trial, 33.26 per cent.

By the mean of four trials on each of the specimens, a yielded of earthy matter 7.37, and b 3.2 per cent. Hence, the proximate constituents are in—

•					Specimen 2.	Specimen b
Moisture	•	•	•	-	0.902	0.888
Sulphor	•	•	•	•	0.202	(not tried.)
Other volatile	matter	•	•	•	39.013	32.372
Earthy matter	•	•	-	•	<b>7.</b> 370	3.200
Fixed carbon	-	•	-	-	52.513	. 63.540
					100.	100.
Velatile to fix	ed comb	oustible	•	•	1:1.346	1:1.9583

In two specimens examined by Dr. King, the total volatile matter was found to be 35.875 per cent. This number, combined with the two above, gave for the average of volatile matter, including moisture, 36.2817. During the trials on evaporation, there were burned 4,132 pounds of this sample, yielding as waste—

Of ashes -	•	•	• ,	•	- 2	8 <b>5.000</b> po	unds.
Of clinker	-	•	• ′	•	- 1	42.250	46
Of soot :	•	•	•	•	•	34.875	66

The ashes contained 13.172 per cent. of combustible matter intermixed; and the soot, of volatile matter, 13.831; fixed carbon, 50.449;

and of ashes, 35.72 per cent. Reducing the ashes and soot in the proportions here indicated, and deducting 4.09 pounds of wood ashes, we obtain 398.93 pounds as the absolute waste from the coal burned. This is equal to 9.655 per cent. Hence, the proximate constituents of the sample are—

Moisture, (from 28 pounds) 1.785 per cent. Other volatile matter, (4 specimens). -34.497 Earthy matter, (from. 4,132 pounds) 9.655 66 Fixed carbon, (calculated by difference) **54.063** 100.

Volatile to fixed combustible 1:1.5672.

The clinker is of a deep iron-gray color, generally in small lumps, with

small shaly portions. It weighs 39.37 pounds per cubic foot.

The calcined clinker becomes of a deep reddish-brown; the ashes, after reincineration, are of a "red-gray" color; the residue of the soot is of a deeper color than that of the ashes, while that left during the analyses of the coal is of a dirty-white color. The ashes weigh 53.40, and the soot 4.91 pounds per cubic foot.

With oxide of lead, specimen a gave 27.285 times its weight of metallic lead; or, deducting 8.272 per cent. for moisture and earthy matter of the

specimen, the lead to one of combustible matter is 29.745.

The trial made in a smith's forge proved this sample to be superior to the average Midlothian coal, then in use in the shops. It gave a good hollow fire, with a moderate amount of cinder, a long flame, and a pretty rapid heat, with less smoke than was visible in the other fires. It did not appear

to affect injuriously the iron to which its heat was applied.

It is unnecessary to state more in regard to the trial of this coal in an office grate, than that it behaved in all respects like the other samples of coal furnished by the Midlothian company—burning with long bright blaze, leaving a coke moderately durable, and producing brilliant jets of highly luminous flame, especially after the coking process had proceeded nearly to its completion.

The time required to bring the boiler into steady action was, on an

average, 1.289 hour.

The average quantity of coke bit unburnt, when the fire became extinct,

was 14.08 pounds.

In noting its behaviour in the furnace, it was remarked that this coal cokes completely, running together into large masses, which cohere firmly during the greater part of the time of combustion, giving off a dense flame with much smoke.

Like nearly all the other samples of coal from the same district of country, it is unfit for use in the blast furnace for smelting iron, without the preliminary process of coking.

#### Remarks on the preceding table of deductions.

The sample to which this table relates was burned at five trials, of which four were made with the chimney 41 feet, and one with it 63 feet high. To prove the relation which exists between the average and the screened coal from the same mines, a comparison may be instituted between the 21st line of this table, and the line having the same number in table CXXXVII. In the last-mentioned table, the 2d and 5th trials are comparable with the 1st and 3d of the preceding table. The mean rate of evaporation by the average coal is seen to be 10.108; that of the screened 8.796 cubic feet of water per hour. It appears from this, that the screened coal was inferior

in activity to the average.

In speaking of the draught of the chimney, in a former part of this report, the causes of the velocity of motion of gases are enumerated, (see page 19.) It may here be added, that the height of a chimney is a most important element in computing the force and velocity of gases flowing through it, and of determining, when all other circumstances are equal, the rate of combustion in any furnace connected with it. The table of deductions now under consideration affords proof of this assertion: On the 19th of May, with a chimney 41 feet high, air plate open, and dainper drawn twelve inches, the combustion was at the rate of 6.013 pounds of coal per square foot of grate per hour. On the 11th of November, with a chimney 63 feet high, damper drawn but eight inches, and air plate also open, the combustion was 8.515 pounds per square foot of grate per hour. The evaporation from the boiler on the 19th of May was 8.583 cubic feet per hour, or 0.754 of a cubic foot to one square foot of grate—the area of the latter being then 11.375 square feet. On the 11th of November it was 14.118 cubic feet of water per hour from the boiler; and as the grate was 14.07 square feet, it was 1.003 cubic foot of water to one square foot of grate. gain in the combustion on a square foot of grate is here 41 per cent.

#### No. 11.

Midlothian average coal, taken promiscuously from a heap procured for use in the smith shops at the Washington navy yard.

On this sample of coal, two imperfect experiments were made while testing the condition and action of the apparatus. Having been performed under considerable disadvantages in respect to the means and appliances for observation, which had not then been fully completed, and without the necessary assistance to take, simultaneously, the several classes of notes, I have not deemed it necessary to detail the observations. In all its external characters, the coal was very similar to other samples from the Midlothian mines.

A quantity of this sample was used in composing the mixtures of Midlothian and Beaver Meadow coals, of which a detailed account has already been given.

The following table shows the composition and other properties of this, as well as other Virginia coals. The per centage of clinker derived from the two trials above referred to, is among the data there recorded. The total waste from one of the experiments was 20.1 per cent. The samples sent for trial by the Midlothian Company gave for the highest result, in waste, 14.83 per cent.; and for the average of four samples, 11.514 per cent.; another evidence of some deficiency in preparing coal for the market.

five, in the second column of numbers, is 28.19; 98. The order of practical evaporative powers is ... ed by the weights of lead reduced by the several

specimens of coal.—See table on page 307.

A series of coals, in which the relation of the fixed to the volatile combustible matter is nearly the same as above, was analyzed by M. Baudin, (as found in his paper in the *Annales des Mines*, 4ème série, p. 85,) and the lead reduced by 1 of the combustible matter of each coal was also determined as follows:

#### CLASS IV.

FOREIGN BITUMINOUS COALS, AND THOSE OF SIMILAR CONSTITUTION WEST OF THE ALLEGHENY MOUNTAINS.—PINE WOOD.

#### SAMPLES.

### Foreign coals.

- No. 1. Pictou, (purchased in New York.)
  - 2. Sidney.
  - 3. Pictou, (Cunard's.)
  - 4. Liverpool.
  - 5. Newcastle.
  - 6. Scotch.

Coals from west of the Allegheny mountains.

- 7. Pittsburg.
- 8. Cannelton, (Ia.)
- 9. Dry pine wood.

#### General characters.

In many respects, this class of coals bears a strong analogy to the preceding. The ratio of the fixed to the volatile combustible matter, is, however, something less. The exterior presents often a resinous lustre. The surfaces of deposition are easily developed by fracture. Great facility of ignition, and a high degree of activity in the combustion of their volatile constituents, are also general properties of this class. Their high proportion of volatile combustible matter renders these coals, when nearly free from sulphur, eminently suitable for the production of illuminating gas; and the tendency of their cokes, with few exceptions, to intuntesce strongly, readers them, in common with the preceding class, highly serviceable in forming large hollow fires for smithing purposes.

### No. 1.

Bituminous coal from Pictou, Nova Scotia, procured from Messrs. Laing & Randolph, in New York, for comparative experiments.

This coal has a glimmering lustre, or a dull aspect, according to the part observed. The surfaces of deposition are, in some specimens, inclined in an angle of 83° to the main partings; thin scales of earthy matter are occasionally found in the joints, or vertical seams; but, in general, little impurity is observable on the exterior. Conchoidal fractures are of unfrequent occurrence. The coal was of average size, lumps and fine being intermixed in due proportion, to constitute a merchantable article for ordinary use in smiths' fires and for domestic purposes. The powder of this coal is of a dark brown color, and its streak on a white earthen ground is of the same tint.

The specific gravity of one specimen (a) was 1.3546; that of another, (b,) 1.2807: from the mean of which, the calculated weight per cubic foot is 82.35 pounds.

By 39 trials in the charge box, the greatest weight of any one charge was 112.25 pounds, or 56.125 pounds per cubic foot. The least weight was 97.5 pounds per charge, or 48.75 pounds per cubic foot; while the average of the whole was 53.548, or 0.6502 of the above calculated weight. The space for the stowage of one ton of the coal is 41.832 cubic feet.

The moisture in specimen a was 0.97; and that in b, 0.935 per cent.

The volatile matter, other than moisture, in a, was 27.51; the sulphur, 0.7689 per cent.

The volatile matter, other than moisture in b, was 20.105.

Four incinerations of a gave of ashes 2.38; and the same number of b, 2.65 per cent.

Hence the composition is as follows, viz:

Moisture	•	Specimen a. 0.970	Specimen 5. 0.935
Sulphur	-	0.769	(not tried.)
Other volatile matter -	•	26.741	` <b>2</b> 0.105
Earthy matter	•	2.380	2.650
Fixed carbon -	•	69.140	76.310
		100.	100.
The volatile to fixed combustible	1	: 2.5132	1:3.7955

Two specimens of this sample of coal were assayed by Dr. King, and yielded the one 36, and the other 33 per cent. of volatile matter, including moisture. These, combined with the above, give a mean of 29.63, which may probably be assumed as a pretty near approximation to the average yield of this ingredient.

By exposure for four days in the steam drying apparatus, 28 pounds of

this coal lost 0.71875 pound of moisture, or 2.567 per cent.

During the four trials of evaporative power, 4153.875 pounds were burned, and yielded 302.4 pounds of ashes, (including those of 408.62 pounds of pine wood.) 253.475 pounds of clinker, and 19.5 pounds of soot.

The ashes lost by reincineration 5.967, and the soot 65.42 per cent. of their weight.

Hence the absolutely incombustible materials are-

From the ashes -	-	•	•	-	284.540	pounds.
From the clinker	<b>-</b> ,	•	.=		253.475	-
From the soot -		•	•	•	6.743

		ı			100.
				1	r <del>ada mere</del> .

Valatile to fixed combustible

1:2.1054

The above result, in earthy matter, derived from a sample of two tons, exhibits a striking contrast with the analyses of single hand specimens.

The clinker is of a dark reddish-brown color, in sheets of considerable magnitude, somewhat porous; small shaly fragments are intermixed, and sometimes adhere to the vitrified masses. It weighed 43.12 pounds per cubic foot, and gained weight by calcination equal to 6.84 per cent., leaving the powder of a light brown, with its finer parts bright red.

The weight of the ashes, as they came from the furnace, was 38.56 pounds per cubic foot; and the residue of their reincineration had a color nearly flesh red, while that from the soot was reddish gray—a shade lighter than

that from the ashes.

The ashes from specimens a and b are of a purplish-red color, with specks of white.

Tried with the oxide of lead, 20 grains of specimen a gave 544.8 grains of metallic lead, or 27.24 times its weight. Deducting moisture and earthy matter, this gives to one of combustible matter 28.184.

In a smith's fire, for ordinary work, this coal afforded a rather dull combustion; made a good hollow fire; left a fair coke, not unusually hard;

produced a large quantity of cinder, and gave a tolerably fair heat.

In the chain shop, it gave a heavy flame; formed a coke too hard to be easily broken up, as the work requires; was rather hard and unmanageable, and left a large proportion of cinder. Sixty pounds made but 11 links of a chain 13 inch in diameter; while several other coals, tried by the same workman on the same chain, were found adequate to the making of from 13 to 20 links, by the same weight of coal.

In grates for domestic use, this coal burns with nearly the same characters as are found in the Virginia coals above described. In heating power, it is exceeded by several of that class. The Clover Hill and Tippeca-

below it; and if those be included with the rest of the ten samples from Virginia, the average heating power is a little above that if the sample now under consideration. The ten Virginia coals gave of water evaporated from 212° to 1 of coal, 8.4777, and the Pictou, 8.4117.

The ignition of this coal is easily effected. It took, on an average of four trials, only 0.937 hour, or 56½ minutes, to bring the boiler to a state of steady action. In conformity with this fact is that relative to the unburnt

roke, which was, on an average, only 5.689 pounds at each trial.

			A DE COMPONICION

### Remarks on the preceding table of deductions.

This sample of coal appears, from the 13th line of the table, to have yielded a rather unusual quantity of clinker. In the first and second trials, when the combustion was at the mean rate of 120.23 pounds per hour, the mean proportion of clinker was 48.428 per cent. of the total waste, or it was 6.452 per cent. of the coal burned. In the third and fourth trials, when the rate of combustion was at a mean of 100.45 pounds per hour, the mean proportion of clinker to total waste was 43.154 per cent., or 5.799 per cent. of the coal burned. The order, in the proportion of clinker throughout the four trials, follows that of the rate of combustion. On three of the four days of trial, it was found necessary, in order to sustain the rate of combustion, to remove portions of clinker from the grate before the conclusion of the experiment. The manometer shows (in table CLV) that at 2h. 30m. p. m., and before the clinker had been removed, the column of mercury was only 0.525 atmosphere in height; while at the commencement of steady action for the day, it had been 0.549. At 3h. 20m. clinker was removed, and at 3h. 30m. the column had already risen to 0.539, which height it retained, with little variation, for 2.5 hours. Again: it will be observed that, on the third trial, (table CLVII,) the mercurial column in the manometer had fallen from 0.545, where it stood at 7h. 45m. a. m., to 0.529 at 0h. 30m. p. m., at which hour the column of "remarks" showsthat "clinker was removed from grate." At 1h. 0m. p. m. the height of manometer was again up to 0.539. From this, in the course of three hours and a half, it again declined to 0.529. These augmentations of pressure are to be understood as having taken place without varying the weights on the safety valves, and merely in consequence of the more rapid generation of steam, and of the increased quantity seeking exit through the limited annular spaces round the valves.

. The period of steady action on each of the first two trials was the same, viz: 6h. 20m. On the one at which the combustion was conducted with air plate open, (August 30,) the evaporation was 14.12 cubic feet of water per hour; with the plate closed, (August 31,) the evaporation was 14.54 cubic feet per hour. It does not, however, appear that this greater rapidity of evaporation was attended with a correspondent increase in the economy of fuel, but the reverse; for at lines 40, 41, and 43, the numbers in the column under August 30 are all higher than the corresponding ones in the next column, under August 31. The amount of the difference in the 43d line (water from 212° to 1 of combustible matter) is 0.2523. But it will be remarked that the gases reached the chimney on the second trial at a considerably higher temperature than on the first, the 39th line showing an excess of the escaping gases over the steam, of 71°.7 on the first, and 105°.1 on the second trial. The analyses of dry gases from the chimney show that on the first trial they were equivalent in heat-absorbing power to 18.833, and on the second to 16.934 pounds of air to the pound of fuel burned. The water derived from the combustion of a pound of fuel on the first day appears to have been 0.2826 pound, and on the second 0.3416. The heat expended on the dry gases required in the combustion of one

pound of combustible matter was adequate to produce 0.1693 pound more of steam on the second day than on the first. The heat employed on the water of combustion from one of combustible, was equivalent to producing 0.0972 of steam more on the second than on the first day of trial. The sum of these differences is 0.2665, or a trifle more than the difference in the evaporative power (0.2523) actually observed in the action of the boiler. Errors of observation may easily account for the excess.

#### No. 2.

Bituminous coal from Sidney, Nova Scotia, sent for trial by Mr. Cunard, agent for the General Mining Association of London.

This coal is of a slaty structure, cleaves easily parallel to the surfaces of deposition, revealing large quantities of carbonaceous clod or mineralized charcoal. The plies of shining coal seen on the surfaces of the main partings are generally very thin. Carbonate of lime occasionally lines the seams of the partings, but not in large amount. The sample was generally in lumps. It shows no great degree of friability, but, on the contrary, requires considerable force to break it. Needle-shaped crystals of sulphate of iron are sometimes found in considerable quantities coating the faces of the coal. When reduced to powder, this coal has a dark-brown color, and the streak it leaves on white porcelain is of the same shade.

The specific gravity of one specimen (a) was 1.3473, that of another (b) 1.3298; the mean giving the calculated weight 83.66 pounds per cubic

foot.

By an average of seventeen trials at the time of burning this sample, the actual weight in the state of lumps was 47.441 pounds per cubic foot, or 0.567 of the calculated weight.

To stow one ton, 47.217 cubic feet of space will be required.

By slow coking, specimen a lost 24.51 per cent. of its weight; and by rapid coking, b lost 29.36 per cent.

The quantity of earthy matter in a was 13.88, and in b 11.083 per cent.

Hence the proximate constituents are—

Volatile matter	,			_	Specimen a. 24.51	Specimen <i>b</i> . 29.360
Fixed carbon	•	-	-	-	61.61	59.5 <b>57</b>
Earthy matter	-	•	•	•	13.88	11.083
	,	,			100.	100.
Volatile matter	o fixe	d combi	astible .		1:2.572	1:2.0285

By exposure in the drying apparatus during the experiments on evaporation, 28 pounds lost 14 ounces, or 3.125 per cent. of moisture. There were burned 1,601.125 pounds of this coal during the two trials; and the ashes withdrawn were 61.25, the clinker 36.50, and the soot 6.25 pounds

After complete The ashes left		- region of	carpon	aceous <u>i</u>	Darticies,	-	52.905 g	oounds.
The clinker	•	•	•	-	~		34.539	66
The soot	. •	•	•	•	•		1.932	46
	Total	-	-	•	•	•	89.376	
From which d	leduct <sub>,</sub> fo	or ashes o	of 431.7	15 pound	ls of wood	-	1.396	æ

Leaves 87.980 pounds of absolutely incombustible matter in the coal, or 5.495 per cent. Hence, admitting the mean of the two determinations of volatile matter above exhibited to give the average of the sample, we may state the composition from this analysis in the large way as follows, viz:

			100.
Fixed carbon (by difference)	•	•	67.570
Earthy matter (from 1,601.125 pounds)	<b>,</b>	-	5.495
Other volatile matter (mean of two trials)	-	•	23.810
Moisture (from 28 pounds)	•	-	3.125

#### Volatile to fixed combustible=1:2.8379.

The ashes from this coal weighed 52.42 pounds per cubic foot, the clinker 40.12, and the soot 3.96 pounds; the last being among the lightest of soots found during the whole series of trials. The volatile and combustible mat-

ter of the soot amounted to 69.089 per cent.

The clinker is black, compact, in thin sheets, evidently highly fusible, spreading over and adhering to the grate bars, with some lighter colored shaly matter generally encrusted by the vitreous portion. The fact of its adhesion to the grate was noticed during the combustion, and the constant high temperature of the bars evinced that the iron of which they were composed was undergoing a species of combustion—possibly by the reaction of the bi-sulphuret of iron in the coal yielding a portion of its sulphur to the metal of the bars.

When pulverized and reincinerated, the clinker left a dark-gray powder, scarcely tinged with red; the ashes produced a tint of red more distinct than the clinker, but the soot left a residuum of the same color as that from the latter. The earthy matter from the two analyses of hand specimens

was almost perfectly white.

Specimen b, above referred to, gave, when treated with oxide of lead, 25.007 times its weight in metallic lead. Deducting 11.083 per cent. of the weight of coal for earthy matter, and 3.125 per cent. for moisture, leaves 0.85792 parts of combustible by which to divide the above number of parts of lead; this gives 29.148 parts of lead to 1 of combustible matter of the coal. The only uncertainty in this result is in the proportion of moisture, which, being derived from the trial on 28 pounds, may not improbably be a little too high for the particular specimen under analysis.

The quantity of coal sent in this sample was too small to leave any portion for trial in grates and smith shops, after the two experiments on evap-

orative power had been completed.

By a comparison of its heating power with that of the preceding and the following samples, (both of which were from Pictou,) it will be seen that

while those two gave of water evaporated by 1 of coal from 212°, 8.4117 and 8.4848, or a mean of 8.4482, this gave but 7.987. The difference, 0.6612, is 7.82 per cent. of the said mean. But as the amount of waste from Pictou coal was, on an average, 12.7168 per cent., while in the Sidney coal it was but 6.01, these two numbers being, respectively, deducted from 100, leave the proportions of combustible matter producing the evaporation of the quantities of water above designated; after this deduction, it will be found that the heating power of the combustible matter in Pictou coal is represented by 9.679, while that in the Sidney is but 8.497, and the difference is 1.182, or 12.21 per cent. of the first number. This points to a distinct character in the combustible matter of each coal.

The steam from 212° to 1 cubic foot of coal by this sample is 378.92 pounds, while by the mean of the two samples of Pictou coal, it is 434.26;

or Sidney is inferior to Pictou by 12.74 per cent.

This coal ignites promptly. In the first trial it was in pretty active combustion in 12 minutes from the time of commencing the charge. It burns rapidly, agglutinates and swells but slightly; its coke falls into small fragments, which facilitates its passage through the grate, and tends to produce waste, unless the interstices be very narrow. It burns with a large and smoky flame, keeping, as already mentioned, the grate bars at a cherry-red heat. The mean time required to bring the boiler into steady action was 1.18 hour, and the mean amount of unburnt coke was 5.9375 pounds. These circumstances indicate great facility in commencing and continuing the combustion.

236°.14 314°.19	The gases appear to have arrived at the chimney, on the second trial, at a temperature 40 degrees higher than on the first.
0.3135 3-61°.565 87°.975 7.0071 7.987 378.93 8.4974 1.423 6,3383	The efficiency of the pound of combustible matter of this coal was lower in the second than in the first trial by 3.6 per coat.

#### No. 3.

Bituminous coal from Pictou, Nova Scotia, sent by Mr. Cunard, agent of the General Mining Association of London.

The coal of this sample is, in every external character, entirely similar to that from the same mining district obtained from New York. The specific gravity of one specimen (a) was 1.3155; that of another, (b,) 1.3352. The mean of these makes the weight of the cubic foot in the solid state 82.835 pounds. The actual weight determined by 20 trials in the charge box is for the least 45.5, for the greatest 52.125, and for the average 49.25 pounds per cubic foot, or 0.5945 of the calculated weight. Hence the space to receive one ton is 45.482 cubic feet.

The moisture expelled by thoroughly drying specimen b was 1.079.

The coking of a caused a loss, including moisture, of 26.413 per cent. The process having been conducted very slowly, the powder did not become agglutinated; but another portion of the same powder, suddenly exposed to a bright red heat, became converted into a well-formed mass. Of specimen b, a portion, coked so slowly and at so low a heat that the gas did not take fire, exhibited a loss of 27.1 per cent. Another portion of the same powder, coked rapidly so as to become completely coalescent, lost 29.34 per cent.

The earthy matter in a was 10.09, in b 11.404 per cent. Hence the proximate constituents of these two specimens are—

Moisture -	(not separ	Specimen a. ately deter	Specimen b. mined) 1.079
Volatile matter		26.413	other than \ 26.021 \ (by slow coking.)
Earthy matter	• •	10.090	11.404
Fixed carbon	•	63.497	61.496
	,	100:	190.
Volatile to fixed co	ombustible	1:2.404	1:2.3633

The moisture expelled from 28 pounds dried in the steaming apparatus, amounted to 0.7812 per cent. The volatile matter, including moisture, from the mean of the two specimens above given, is 26.756.

During the two experiments on evaporation, there were burned 1,962.5 pounds of this coal, and the—

Weight of ashes with	idrawn v	vas	•	<i>;</i> •	116.00 p	ounds.
Weight of clinker	•	•	•	•	121.75	66
Weight of soot -	• .	•		• •	8.75	<b>66</b> ·•

The ashes lost 0.04077 of their weight, and the soot 0.60144, by reincineration. Reducing the weights of these two, and deducting 1.029 pound for the ashes of 355.25 pounds of pine wood, we have left 245.481 pounds for the total waste from the above weight of coal, or 19.508 per cent.

### From these data it would seem that the coal is composed of-

Moisture (from 28 pounds)	-	•	0.7812
Other volatile matter (from two specimens)	•	•	25.9753
Earthy matter (from 1,962.5 pounds) -	•	•	12.5085
Fixed carbon (calculated by difference)	•	•	60.7350
· · · · · · · · · · · · · · · · · · ·			

100.

Volatile to fixed combustible 1: 2.5929.

The ashes weighed 39:01 pounds per cubic foot.

The clinker " 38.00 " " " The soot " 3.82 " "

When reincinerated or calcined, the clinker became of a dark-drab or ight-brown color, the ashes of a light reddish-gray, and the residue of the soot a light-drab color. The ashes from analysis of a were pure white; from b, dirty white.

The clinker, as it came from the furnace, was black, vitreous, and porous, in masses tolerably friable, and not apparently prone to adhere to the grate.

Much shaly matter attaches itself to the vitrified portions.

With the oxide of lead, specimen b gave 23.355 times its weight in metallic lead. Deducting moisture and earthy matter, we have left 0.87517 of combustible; by which, dividing the above, we get  $\frac{2.3 \cdot 3.5}{87.5} = 26.686$ .

For the reason assigned in regard to the preceding sample which accompanied this, the trial in smith's forges and in open grates was necessarily dispensed with. This is the less to be regretted in the present instance, as the sample of Pictou coal already described has been tested in the forge; and as the action of the two samples is in other respects almost identical, there is no reason to doubt that in this particular also they would be found to coincide.

The mean time required to bring the boiler to a steady rate of evaporation was 0.85 hour, or 51 minutes. The weight of coke left unburnt on the grate was very small, being on the first trial 5 pounds, and on the second 2.5. The combustion commenced promptly, and the flame was long, and recompanied by considerable smoke. The large amount of clinker (more than 50 per cent. of the total waste) rendered it necessary to remove the heavier masses within a few hours after the fire was kindled.

## TABLES CLXIII, CLXIV.

Pictou (N. S.) coal, (Cunard, agent.)

Averages.	Remarks.
3.75 49.25 138.43 9.836 12.0625 6.1927 51.141	In a very close approach to total combustion, as well as in many other of its pace-erties and modes of action, this sample manifests its affinity with the Pictor conference in New York.
1029.77 16.4735 2.7275 7.4664 . 7.43 6.3782	The rate of evaporation with air plate open is 16.5 per cent. ess rapid than with the plate closed.
221°.14 312°.5	With the air plate open, as in the second trial, the gases going to the chimney had a temperature 35° higher than with the same plate closed, as in the first experiment. The considerable coating of soot on the flues may have helped to keep the gases at their high temperature, and to diminish the evaporative effect, as seen in lines 41 and 43.  The second trial had the advantage of a stronger draught than the first.

#### No. 4.

Bituminous coal from Liverpool, England, procured from Laing & Randolph, in New York, for comparative experiments.

This coal has well-defined partings, and surfaces of deposition remarkably even, along which fractures very frequently occur. Its main partings I found to be generally from 85° to 87° inclined to the horizontal seams. The lustre is resinous or pitchy in some fractures, and shining in others; while the mineralized charcoal in the horizontal seams gives them, of course, a dull aspect. Few or no exterior indications of impurity are visible. Its powder is of a dark brown color.

The specific gravity of one specimen (a) was 1.254; that of another (b) 1.2706; the mean of which indicates 78.89 pounds as the weight of one cubic foot. Forty trials in the charge box gave as the maximum 51.5, the minimum 45.75, and the average of the whole 47.878 pounds per cubic

foot; which is 0.6069 of the calculated weight.

This average shows that 46.786 cubic feet of space will be required for one gross ton.

The moisture in specimen  $\alpha$  was 1.758; that in b 1.628.

The sulphur in a was 0.3762.

When coked very gradually, a gave of volatile matter, including moisture, 32.89; and when coked pretty rapidly, b gave 36.41 per cent. of the same material. Another comparative trial of the effect of slow and rapid coking was made by coking a rapidly, which caused it to lose 41.14 per cent., and b slowly, whereby it lost only 33.05. Taking the mean of the trials by the two methods, a gives 37.015; b gives 34.73.

Two specimens tried by Dr. King, both by rapid coking, gave 40.333 for the first, and 40.625 for the second, or a mean of 40:479 per cent. of volatile

matter, including moisture.

By the mean of four incinerations, a gave of earthy matter 1.12, and b 2.94 per cent.

Hence the composition of these two specimens may be stated as follows

Moisture Sulphur	-	- -	-	-	Specimen a. 1.785 0.376	Specimen b. 1.628 (not tried.)
Other volatile	e matter, coking	, by me	an of ra	pid }	34.854	34.730
Earthy matt	_	-	•	•	1.120	2.940
Fixed carbon		-		-	<b>6</b> 1.865	60.702
					100.	100.
The volati	ile to the	e fixed	combust	lible	1:1.756	1:1.748

Admitting that the moisture in the two samples tried by Dr. King was equal to that derived from the 28 pounds, the combustible portion would be 40.479—0.892=39.587 per cent.

During the trials of its evaporative power, there were burned of this coal

3,786 pounds.

The ashes withdrawn amounted to 120.5, the clinker to 71.75, and the soot to 18.25 pounds.

By reincineration, the ashes lost - - - 16.93 per cent.

"the soot - - 71.69 "

while the clinker gained a little by calcination.

The ashes of 654.74 pounds of wood was 2.01 pounds.

Making the reductions here indicated, the total incombustible matter recovered, and which was derived from the coal alone, was 175 pounds, or 4.622 per cent. From these data, entirely independent of the above analyses of a and b, we have the composition of the sample as follows:

Moisture, from 28 pounds -	-	•	- 0.892
Other volatile matter, by two specim	ens	•	- 39.587
Earthy matter, from 3,786 pounds	•	•	- 4.622
Fixed carbon, by difference -	•	•	- 54.899
			100.
Volatile to fixed combustible -	•	•	- 1:1.513

The earthy residuum, from the analyses of the two specimens a and b, was of a dark brown color. The clinker was compact, of a reddish brown color, not in large masses; vitrified, but containing small bits of light slaty matter. When pulverized and recalcined, it became of a deep brown, or dark red color.

The residue from reincineration of the ashes is rather lighter red than that of the clinker, while the soot gave a still lighter colored ash, but not lighter than that of ordinary hard-burned brick.

The weight per cubic foot of the several residua, as drawn from the fur nace, was as follows, viz:

Ashes	•	-	•	•	•	•	53.70	pounds.
Clinker	•	•	•	•	•	•	40.12	66
Soot	•	-	•	•	•	•	3.92	66

When tested with the oxide of lead, specimen a yielded 27.074 times its weight of metallic lead; and this, after deducting moisture and ashes, gives of lead to 1 of combustible 27.884.

In the chain shop, 60 pounds of this sample were sufficient to make 13 links of a chain 1 inch in diameter; gave a good fire for the purpose, and yielded but a moderate quantity of cinder.

In the anchor shop, where it was tried on ordinary smith's work, it gave a good hollow fire, and worked in a manner highly satisfactory in regard to its action on the iron.

In an ordinary domestic grate, it takes fire promptly; burns, as in the furnace, with a long flame, accompanied with much smoke; swells up, and cements into a spongy mass, leaving a light porous coke.

The time required to bring the boiler into steady action was-

In the first trial	•	•	•	•	-	0.833 hour.	
In the second trial	•	•	. •	•	•	0.750	66
In the third trial	•	•	•	•	•	0.366	æ€
In the fourth trial	-	-	•	-	-	1.500	"
Mean -	-	•	-	-	•	0.862	"

The weight of coke left after each trial was 11.06 pounds.

### Remarks on the preceding table of deductions.

In examining the second and third columns of this table, it will be observed that the rate of combustion with a 4-inch damper was but 6.505 pounds per square foot of grate per hour; while on the preceding trial, with an 8-inch damper, it had been 9.912 pounds. Hence the diminution in combustion, by throttling the smoke, was 34.2 per cent. The 13th line shows that on the third trial (with a 4-inch damper) the total waste was 5.97 per cent. of the coal; whereas the second trial had yielded but 4.80 per cent., or the augmentation of waste was 24 per cent. of the latter number.

The rate of evaporation fell from 2.585 pounds per square foot of heated surface per hour (as seen in line 22) on the second trial, to 1.386 on the third. The loss in rapidity of evaporation is 46.3 per cent.; from this deducting the loss in rapidity of combustion, we obtain 12.1 per cent. as the actual loss in useful effect of the fuel. This, it will be observed, is obtained from the approximate results derived from the period of steady action.

The same conclusion follows, however, from data entirely independent of the preceding. Thus the 43d line shows that on the second trial the unit of combustible matter evaporated from 212°, 8.302 of water, and on the third trial only 7.2854; the difference, 1.0166, is 12.2 per cent. of the

larger number.

The air reached the grate at a temperature 337.25—302.45=34°.8 hotter on the third than on the second day of trial—an effect due to its slower movement, and the consequent higher temperature of the inner walls through which it received its heat. This shows that the higher temperature of the air which supplies the furnace is not alone sufficient to secure a more perfect combustion.

It also appears that the gases left the boiler and passed into the chimney on the second day of trial at 346°.55, and on the third at 279°.06; so that they did not carry away more, but, on the contrary, 67.5 less heat in the

latter case than in the former.

The imperfection of combustion, consequent on a want of sufficient air to consume the gaseous products, is here the obvious source of inferiority in result. Both the second and the third trials, it will be observed, were made with air plate closed.

A comparison of the first with the fourth trial shows what effect is to be attributed to the soot of the flues from three days' operations in diminishing evaporative efficiency. Both trials were made with air plate open, and the upper damper drawn 8 inches. The coal burned per hour on the first day was 136.98, and on the fourth 115.25 pounds. The difference is 15.8 per cent. of the former number. The rate of evaporation was 16.592 cubic feet per hour on the first, and 13.16 on the fourth trial. difference, 3.432 cubic feet, is 20.7 per cent. of the larger number. From this deducting 15.8, the remainder, 4.9, indicates the loss of useful effect of the fuel in consequence of the imperfect conduction of the coating of the This is a result from the observations during the period boiler and flues. of steady action. In line 43 is found 8.9827 in the column of the first, and 8.4511 in that of the fourth trial. The difference of these, 0.5316, is 5.9 per cent. of the larger number. The approximate result from steady action, and that from the final amount of evaporation, again confirm each other in their general indication, and differ but by 1 per cent. in the proportion of loss.

Bituminous coal from Newcastle, England, procured for comparative experiments, from Messrs. Laing & Randolph, of New York.

In many of its external characters, this coal strongly resembles the Midlothian and Chesterfield coals of the Richmond district. Its planes of deposition are not always followed by the cleavages in that general direction. Some unevenness frequently occurs, revealing conchoidal surfaces of a pitchy appearance. The main partings are mostly at right angles to the horizontal seams. Scales and laminæ of carbonate of lime, and probably of magnesia, exist throughout the partings. They effervesce moderately with nitric acid. Sulphuret of iron is seen in contiguity with this earthy deposite. When reduced to an impalpable powder, this coal has a light brown color, indicative of high bituminousness.

The specific gravity of one specimen (a) was found to be 1.2844; that of another, (b,) 1.2291; the mean of the two giving the calculated weight

per cubic foot, 78.54 pounds.

Forty trials in the charge box, of which the *least* result was 48.375, and the greatest 53, afforded an average of 50.8218 pounds per cubic foot, or 0.647 of the calculated weight. The space required for one ton is, consequently, 44.076 cubic feet.

In specimen a the moisture was 0.993, and in b 0.926 per cent.

Twenty-eight pounds dried in the steaming apparatus for four days lost

9 ounces, or 2.007 per cent.

The sulphur obtained from b was 0.23 per cent. Of volatile matter other than moisture, a gave 33.597; and b, by the mean of two trials, gave 40.355 of volatile matter, including moisture and sulphur.

The earthy residuum of a was 3.75, that of b 1.85 per cent.

Hence, the proximate constituents of these two specimens may be stated as follows:

	Specimen a.	Specimen b.
Moisture	- 0,993	0.926
Sulphur	- (not tried)	0.230
Other volatile matter -	- 33.557	<b>39.199</b> .
Earthy matter	- 3.750	1.850
Fixed carbon	- 61.700	57.795
	100.	100.
Volatile to fixed combustible	- 1:1.8387	1:1.4744

The pasty state into which the coal is brought during the coking process, causes portions of gas to become temporarily confined within the semi-fluid mass. When, at length, these become sufficiently elastic to burst the enclosure, jets of flame, accompanied with smart explosions, and possessing a high illuminating power, are frequently observed. In these analyses it was found expedient to confine the lid of the platinum crucible, to avoid its being thrown off by the cause just referred to.

The total volatile matter from two specimens tried by Dr. King was 39.083 and 38.125, respectively, or a mean of 37.604. Combined with the two above given, this result would afford for the total volatile matter 37.528.

During four trials of evaporative	power, th	nere were	burned 4,023	lbs. of
this coal, yielding, of—	•		•

And the	ere re	main of	incomb	ustible i	matter o	f the		
coal		- ,	•.	•	•		217.232	66

= 5.3997 per cent.

From these data, we may infer that the sample had the following proximate constituents:

Earthy matter, (from 4,023 lbs.) Fixed carbon, (calculated by difference)	5.400 56.996
	100.

Volatile to fixed combustible 1:1.6011.

The ashes derived from this sample weighed 51.11 lbs. per cubic foot; the clinker, 38.25; and the soot (which, with a single exception, is the lightest obtained from any coal examined) weighed but 3.7 lbs. per cubic foot.

The clinker is in thin sheets, of a dark color, with small portions of slaty residuum, whitening the otherwise nearly black compact vitrified masses. It is highly fusible, and adheres to the grate.

By means of the oxide of lead, specimen b produced the reduction of 26.785 times its weight of metallic lead; which, after deducting 2.776 parts for moisture and ashes, gives for one of combustible matter in the coal 27.55 times its weight of lead.

This coal was submitted, in addition to the above trials, to the following analysis:

Forty specimens were selected from the different casks-about an equal number from each. A small fragment was detached from each specimen, and the whole were pulverized together. Of the fine powder, 55.9 grains were placed on a platinum capsule, to incinerate in the muffle of an assay furnace, where it became completely reduced, leaving only 2.1 grains, or 3.756 per cent. of waste.

Of the same powder, 102.5 grains were thoroughly dried at a tempera-

ture below 250°, losing thereby 1.38 grain, or 1.346 per cent.

The same portion, closely covered, was then coked slowly, and finally kept for some time at a full red heat in the muffle, till all inflammable matter had ceased to escape; after which, it weighed 72.1 grains.

This shows that the total volatile matter, by this mode of treatment, is 29.658 per cent.

Hence	, the	proximate	constituents are—
		<b>4</b> - •	

Moisture -	•	•	-	•	•	- 1.346
Other volatile m	atter	•	•	•	•	- 28.312
Earthy matter	•	•	•	•	-	- 3.756
Fixed carbon	•	-	-	•	•	- 66.586
			•			
						100.

And volatile to fixed combustible - - - 1:2.3519

In all the other determinations of volatile matter, the method of rapid coking was pursued; and the difference, as above seen, is very striking. By rapid coking, the weight of coke obtained from specimen a, above analyzed, was less by 6.95, and that from b by 15.21 per cent., than from the average specimen just presented.

This coal was also subjected to analysis by the scale oxide of copper.

109.5 grains were thoroughly dried, and proved that the moisture had been 1.6 grain, or 1.461 per cent.

The same specimen had been found to contain 1.85 per cent. (of the raw coal) in earthy matter, which is 1.877 of the dried coal.

6.46 grains of this dried coal, containing 0.1212 grain of ashes, gave—

U		•	•		O	•	U
Of water -	•	•	•	•	•	3.21 gr	ains.

100.

· [ 386 ] 500

If, from the data furnished by this analysis, we would calculate in the usual way the heating power of the raw coal, we must first deduct from the weight of hydrogen (5.439) one-eighth the weight of oxygen, (1.2348 grain,) which leaves of that combustible 4.2042 grains; and if, with Despretz, we adopt for the heating power of hydrogen 42559° Fahrenheit, (236400 centigrade,) then will 1789° express the heating power of this ingredient. And if, with the same author, we admit the heating power of carbon to be 14040° Fahrenheit, (7800 cent.,) then 0.81371×14040=11424°, will represent the heating power of the carbon present, supposing it to be converted into carbonic acid. The numbers 11424+1789=13213, express the pounds of water capable of being heated 1° Fahrenheit by the combustion of 1 pound of the raw coal; and in order to convert this into terms of the standard employed in the researches on evaporation, it is only necessary to divide this number by 1030, the latent heat of the vapor of water, which will give the theoretical evaporative power of the pound of coal, equal to the production of 12.828 pounds of steam from water at 212°. Now, the maximum evaporative power obtained was 9.0706 pounds of water from 212°, to 1 pound of coal burned. The difference of these two is 29.29 per cent. of the theoretically computed heating power.

If, instead of the numbers given by Desprets, we prefer those obtained by Dulong, viz: 62535 for hydrogen, and 12906 for carbon, the calorific power of the former will be 0.042042 × 62535 = 2629; and that of the latter, 0.81371 × 12906 = 10521; and the sum of these two, 13150, differs but

little from the number obtained from using the data of Despretz.

No experiments were made on the gases passing into the chimney while burning this coal, so that I am not able to present the total heating power expended on the air which supplied combustion, the moisture of that air, and the water generated from the coal itself, as has been done in a subsequent table with regard to many other samples. If, however, we compare the effect produced by coals nearly analogous to it, and which have been tried in that manner, it will be evident that this theoretical result of 12.828 pounds of water to 1 of highly bituminous coal, was in no instance eyen approached. Seven trials on the Middothian coal of Virginia gave for the heating power, measured by the steam alone, 8.4786, and by all the means in the coal of the difference, 1.59, is only 15.78 per cent. of the

It seems not to have been considered, by those who have rmine the heating power of fuel for practical purposes, by efficiency of its hydrogen constituent, that the hydrogen on a have operated to demonstrate its heating power had alught to the elastic state, at the expense of a large quantity ced to the latent state; while in fuel, it is either in the solid at the commencement of the process of combustion. The

To compare the evaporative power of the unit of combustible matter in Newcastle coal, as determined by the actual evaporation, with that derived from the carbon found in its combustible ingredients, as proved by ultimate analysis, recourse is had to the average in the 43d line of the table of deductions, which is 9.1777; and as, by what is stated in the text, this may be taken for 1—0.1578 ne0.8423 of the total evaporative power, therefore 9.1777—0.8422 m10.898 methat total evaporative power of the unit of combustible matter in the east, as present by the steaming operations. And as 0.84157 is the proportion of carbon in 1 of the combustible matter of the coal, by altimate analysis, therefore 10.845 × 12906

10.80

In addition to the above researches which have been made

practical bearing of this difference becomes the more important in cases where the products of combustion necessarily pass away from the surfaces to be heated, at a temperature above boiling point. The vapor of water at ordinary atmospheric pressure has the same bulk as the hydrogen from

which it had been ger in forming it, had onl **bon, forms** carbonic a condensed into it. Ir. Rumford, the watery employing cold surfac the vapors generated can this be considered **steam** boiler. Of coking coal from South Hetton, he found the composition to be-

Carbon Hydrogen Oxygen and Ashes	asote	-	:	•	5,171 9.086	Deducting Carbon Hydrogen Oxygen and		•	85.425—14.287 5.304— 5.304 9.369— 1.166
					00.				

My specimen will be found to have been much measure the Metton than the Garcefield specimen of Mr. Richardson.

### Remarks on the preceding table of deductions.

With the air plate closed, and damper drawn 8 inches, the rate of evaporation on the second day of trial (September 7th) was 16:01 cubic feet of water per hour, while on the third trial, (September 8th,) with the air plate likewise closed, and the damper drawn only 4 inches, the evaporation was 10.67 cubic feet per hour. The falling off in rapidity of evaporation is therefore 33.3 per cent. It appears also that the fuel was burned with less economy on the third than on the second day of trial. Same line (43d) shows the evaporative effect of one of combustible matter to have been 9.2579 on the second, and but 8.6074 on the third. The difference amounts to 7 per cent. of the larger number. The dense smoke which passed out of the chimney on the third trial, (see column of "remarks," table CLXXIII,) indicates the cause of this diminution of useful effect. slow passage of air towards the grate, retarded as it was by the partly closed damper, caused it to arrive there with a temperature, on the third day's trial, of 359°, instead of 301°, which the air had possessed on the preceding day.

The longer continuance of the products of combustion about the absorbing surfaces of the boiler caused them, on the contrary, to quit the horizontal flue, and pass into the chimney with a mean temperature of only 326°.8, instead of 363°.5, as on the preceding day. From this last remark it appears that we cannot refer the loss of useful effect to the superior temperature of the escaping gases. It must be sought for in the imperfection of the combustion carried on in the furnace, while the smoke was throttled by the

damper drawn only 4 inches.

The fourth trial, with damper drawn 8 inches, and the air plate open, was intended as a repetition of the first, and was designed to afford the means of ascertaining what effect the sooty lining of the flues, derived from three days' previous combustion, would produce on the heat-absorbing power of the boiler. That effect is apparent, both in the temperature which the products of combustion carried to the chimney, and in the evaporative power of the unit of combustible matter. They are seen at lines 30 and 43; in the former of which it is shown that the gases reached the chimney during the first trial at 318°.23, and during the fourth at 408°.07; and in the latter, the evaporative power is found to have been 9.6424 on the first, and but 9:202 on the fourth. The difference (0.4404) is about 4.5 per cent. of the useful effect derived from the fuel when the flues were entirely To know whether the higher temperature of the products of combustion is adequate to account for the lower evaporative efficiency of the combustible matter, it may be assumed that the weight of air equivalent in its capacity to absorb heat to that of the products of combustion from one pound of combustible matter of this coal, was the same as that found on the fourth trial of Liverpool coal, viz: 19.888 pounds. As the gases passed away 89°.34 hotter on the fourth day than on the first, and as the specific heat of air is 0.267, the following computation gives the evaporative power of the heat thus expended, viz:  $(19.888 \times 89.84 \times 0.267)$  + ""1080 = 0.4032. This proves with sufficient exactness that the cause as-""'Bigned is windly sufficient to account for the effect observed.

#### No. 6,

Bitumineus wal from Scotland, processed for trial and comparison with American contraffrom Mesons Lating & Bandelph, New York.

The exterior app. In some, it 'is that of want of fustre, its coring the surfaces of dor shining lustre of a are completely defin Carbonate of lime a numerous little diker of cannel and foliate specimen. Hence it

where these characters co-exist. If seems probable that considerable diversity exists in the composition of different plies of the seam or bed from

which it was derived.

In some of our Western States, similar diversities in the appearance of

coal from the same bed are to be met with.

The specific gravity of one specimen (a) was found to be 1.5834; that of another (b) was 1.4552. By the mean of these, the calculated weight per cubic foot is 94.955 pounds. Thirty-eight trials in the charge box proved the actual weight to be 51.092 pounds, or 0.538 of the calculated weight. The space for stowing one ten is 43.843 cubic feet. The maximum weight of a cubic foot by trial was 56.375, and the minimum 46.125 pounds. The mean of these two, 51.25, is very near the above average of the whole humber of charges.

The moisture found in specimens a and b was precisely the same, viz: 2.049 per cent. By exposure for four days in the steam drying bath, 28

pounds of this sample lost 13.5 ounces, or 3.013 per cent.

The sulphur in b was 0.3582 per cent.; and the volatile matter, other than moisture, expelled by coking, was 37.281; while that from a was 28.311 per cent.

The earthy matter in a was 12.325, and that in b 14.87 per cent. Hence

we have the composition of-

In moisture In sulphur In other volatile matter In earthy matter In fixed carbon	Specimen a.  - 2.049 - (not tried) - 28.311 - 12.325 - 57.315	8pecimen 6. 2.049 0.358 36.923 14.870 45.800
Volatile to fixed combustible	100.	100.

Specimen b had an aspect decidedly like that of cannel coal, and was largely interspersed with lamines of carbonate of lime in the partings. In the incinerations of b, (in which portions of the powder were placed in four different platinum cups in the same muffle,) the cup which had been in the hottest part had lost more than any of the rest, and the per centage of residue followed the reverse order of the temperatures to which the cups had

been exposed. The order is that of the following numbers, beginning with that which had been in the hottest part: 13.86, 14.97, 15.10, and 15.39. The complete reduction of carbonaceous matter does not necessarily imply

nposition of the earthy carbonates, for which a very strong required. If hydrated argillaceous substances exist in the is of the coal, they may require a still higher temperature to ortions of water.

matter, including moisture, obtained from two specimens of by Dr. King, amounted to 41.85 per cent.

of coal burned during the four trials of evaporative power, ids. The ashes withdrawn were 175.5, the clinker 220.25, .375 pounds. When completely reincinerated, the

In all - - 363.27 " " "

From which taking the ashes \ of 981:25 pounds of wood \ = 2.83 " " " "

: Leaves the incombustible matter from the coal alone = 360.44 pounds=9.3378 per cent.

From these data may be derived the following composition of the coal of this sample:

Moisture, from 28 pounds - - 3.013
Other volatile matter (two specimens) - - 38.337
Earthy matter, from 3,860 pounds - - 9.338
Fixed carbon, by difference - - 48.812

Volatile to fixed combustible 1: 1.2569.

The ashes weighed per cubic foot 47.94, the clinker 39.87, and the soot

**8.65** pounds.

The clinker is in general black, with some whitish portions of slate adhering. It was in sheets of considerable magnitude, and produced so much obstruction of the grate, as to require removal once or twice in the course of a day's operations. The slaty portions preserve, in many specimens, the original forms of their masses.

The color of the residue, after reincinerating the pulverized clinker, was a light gray, very slightly bordering on red; of the ashes, dark brown; of the soot, light yellowish gray; while that derived from analysis was of a

dark brown, or deep "ashen" gray.

A trial of specimen b, with the oxide of lead, yielded 22.7 of lead reduced by 1 of raw coal employed; and, deducting 0.16919 for moisture and ashes, this gives 27.03 of lead to 1 of combustible. Had the whole combustible matter been carbon, its reductive power would have been 0.36981 × 34=28.553. Hence the actual reductive power was 5.2 per cent. less than it would have been had the whole been carbon, instead of containing a large proportion of hydrogen.

A specimen of the dannel variety was submitted to analysis with the scale oxide of copper. It had a specific gravity of 1.2759;

Possessed of moistre to 250° for half a				ng }	1.365 p	er cent.
Of other volatile m		•	•	-	35.586	· « ()
Of earthy matter	-	<b>-</b> .	, •	•	2.707	"
Of fixed carbon	•	•	-	•	60.342	46
. •		•				
•		-	-	•	100.	., 1

And having, therefore, the fixed to the volatile combustible in the ratio of 1.6957 to 1.

Of this specimen, dried in fine powder as above, were taken 7.64 grains; of which the earthy matter was 0.2097 grain, and the combustible part was, consequently, 7.4303 grains. Submitted to analysis with all the usual precautions, this gave of carbonic acid 22.6, and of water 3.75 grains. Admitting 6 to be the atomic weight of carbon, this gives—

Carbon Hydrogen	•		6.1636 grains. 0.4166 "
Of which the sum - And this deducted from -	-	• =	6.5802 " 7.4303 "
Leaves of oxygen and azote	-	<b>-</b>	0,8501 "

As 7.64 grains of dried coal are equivalent to 7.7457 grains in the raw state, the above data afford the following as the ultimate constitution of this specimen in that condition, viz:

· . · · · · · · · · · · · · · · · · · ·	•		•				100.
Ashes	•	•	•	-	•		2.707
Oxygen and a	azote	•	-	-	-	-	10.976
Hydrogen	•	•	•	•	-	•	5.378
Carbon	•	-	<b>-</b> ,	•	•	•	79.574
Moisture	<b>.</b>	-	-	-	•	=	1.365

If the moisture and ashes be deducted, the relation of the remaining constituents to each other is—

Carbon -	•	•	•	82.952 =	13.825	atoms.
Hydrogen -	. •	<b>,</b> •	•	5.607 =	5.607	"
Oxygen, &c.	-	•		11.441 =	1.430	68, 1
	·		. 1	100.		

As the above analysis shows the total carbon in the raw coal to be 179.574 per cent., and the previous trial had given the fixed carbon equal to 66.942, it is evident that the difference (19.232) must have been the

portion velatilized in the process of coking; so that the velatile matter must have consisted of—

Carbon - 19.232

Hydrogen - 5.378

Oxygen and azote - 10.976

In 35.586 parts obtained in the first analysis.

One-eighth of the oxygen in the raw coal is 1.372 grain; which deducted from the hydrogen, (5.378,) leaves 4.006. Hence, to compute the heating power of the raw coal by Despretz's numbers, we have—

For the hydrogen - 0.04006  $\times$  42552 = 1704.6 For the carbon - 0.79574  $\times$  14040 = 11172.0

The sum of these - = 12876.6

And this, divided by the degrees expressing the latent heat of the vapor of water, (1030°,) gives 12.501 pounds of water which ought to have been evaporated from 212° by one pound of the raw coal, on the supposition that the whole heating power had been employed in producing that effect; whereas the maximum effect of one pound of the coal burned under the steam boiler was but 7.476, and the average of four trials only 6.946 pounds of steam generated from that temperature.

By adopting the numbers of Dulong, we have—

The heating power of the hydrogen carbon 0.04006 × 62535== 2505 0.79574 × 12906== 10270

Or the total heating power is - 1277.

This shows still a wide departure from the practical result. Expressed in evaporative efficiency, it amounts to 12.402, instead of 12.501, as above.

By reference to the table exhibiting the analyses of gases drawn from the chimney, it will be seen that three trials on that subject were made while burning the Scotch coal; and under the title of deductions relative to the heating power of fuel, in the same table, will be found the evaporative power of the heat employed on all the absorbents; that is, on the escaping gases, the water from combustion, the hygrometric moisture of the air, and the water in the boiler. The average number is 8.464, and the maximum 8.868. These numbers would be increased to 9.7412 and 10.906, by computing for one of combustible in the coal burned; that is, after deducting 3.013 for moisture, and 10.098 for mean amount of waste left after the fire was extinct.

The heating power of one of combustible in the analysis, is found, in like manner, by deducting the moisture and ashes found in the specimen assayed, and dividing by the remainder the numbers already given. Thus, 1—0.04072=0.95928; and 12876+0.95928=13423, by the numbers of Despretz; 12775+0.95928=13317, by those of Dulong.

If from the mean of these (13370) be deduced the evaporative power, it amounts to 12.98; from which taking 10.206, the remainder (27774) will be 23.665 per cent. of that mean. We cannot suppose this deficiency to have been due to the carbon wasted in the smoke, since the amount of

welaffizable carbon altegether is but 19.232 per cent. of the coal, or 20.048

per cent, of the combustible matter.

From the proportion of the three combination ingredients already presented, the separate calorific and evaporative powers of the carbon and hydrogen are deduced, as follows, from the numbers given by Dulong: (0.82952 × 19906) ÷1030=10.393 of steam from the carbon in 1 of combistible; and (0.04177 × 62535) ÷1030=2.535 of steam from the hydrogen in 1 of combustible. And as we have obtained, by experiment in the large way, 10.206 of steam power from 1 of combustible, it should seem (if Dulong's number can be relied on) that the weight of carbon in this coal is the measure of its heating power.

No. 7.

# Bituminous coal from Pittsburg, Pennsylvania, sent for trial by Mesers. W. T. Hepp & Co., of New Orleans.

The following letter relates to this sample:

" NEW ORLBANS, July 12, 1842.

" To the United States Navy Agents; Washington city, D. C.:

"Gents: We take the liberty of forwarding a bill of lading for one cask Pittsburg coal, as a sample, which we believe you will find to be a superior article. In this city it is preferred to any foreign coal yet introduced in our country, and superior to any other American bituminous coal as yet discovered. The article has been fully tested by the steamers running from this port to Havana and Texas.

"We propose furnishing the Government with any quantity she may require at this place for \$6 50 per ten, or at Pensacola at \$9 per ton. Should you require any further information, we shall be happy to receive

any communication on that subject from you.

"In the mean time, please acknowledge receipt of the cask of coal, and your opinion thereon.

"We are, very respectfully, your obedient servants,

"W. T. HEPP & Co."

The above letter was not received until after the experiments had been completed, and then as a duplicate in answer to an inquiry made relative to the origin of the coal. The sample consisted of about two hundred weight—scarcely enough for a bare trial under the steam boiler; and cer-

tainly not enough for a full development of its properties.

In external characters, it is an almost exact counterpart of the Newcastle coal of England. It has the same resincus lustre, the same exhibition of fossil remains and carbonaceous matter in the surfaces of deposition, the same position of the main partings at right angles to the
surfaces just mentioned, and, of course, the same tendency to break into
cubical masses. It exhibits less earthy matter in the partings, and seldom shows any trace of pyrites on the surface. Other resemblances will
be observable in the following description of analyses and tests to which
it was subjected.

The specific gravity of one specimen (a) was 1.23, that of another (b) 1.2747; the mean of which affords the calculated weight per cubic foot 78.275 pounds. Two trials only could be made in the charge box, the mean of which affords the weight per cubic foot 46.8125, or 0.598 of the calculated weight. The calculated space for the stowage of a ton is 47.85 cubic feet. The moisture found in the two specimens was exactly the same in amount, being 1.397 per cent. Of volatile matter other than water, a gave 32.783, and b 30.293 per cent.

The sulphur in b was 0.1598 per cent.

Five trials by Dr. King gave a mean result in volatile matter of 38 per cent. These were all conducted on the plan of rapid coking, and gave, doubtless, higher proportions of volatile matter than if the process had been carried on more gradually.

In specimen a, the earthy matter by four trials was 4.17, and in b by eight trials it was 3.26 per cent. The composition of these specimens may, therefore, be stated as follows:

	Specimen a.,	Specimen b.
-	- 1.397	1.397
-	- (not tried)	0.16d
-	- `32.783 ´	30.133
, <b>-</b>	- 4.170	3.260
-	- 61.650	65.050
	100	100
	100.	100.
-	- 1:1.8805 1	: 2.1473
-	- 1:2.01	39
		1.397 - (not tried) - 32.783 - 4.170 - 61.650 - 1:1.8805

During the single brief experiment on evaporative power, the weight of coal consumed was 208.38 pounds; the ashes derived from it 15.5, and the clinker 2 pounds, while the soot from the flues was 1.75 pound.

The ashes lost by	y reinci	neration	•	•	•	21.123 p	er cent.
The clinker	•	-	•	•	•	13.240	<b>CK</b> ,
The soot -	•	•	-	•	-	37.650	68

Making these reductions, and deducting 0.311 pound of wood ashes from 101.5 pounds of wood used in commencing the experiment, there remain 14.741 pounds of incombustible matter, which, divided by 208.38, gives 7.0741 per cent.; which shows that the earthy matter in the specimens above shalyzed was but about half as much as the average of the sample.

The ashes from the analyses of this coal were of a grayish or yellowish-white color; the pulverized and reincinerated clinker was of a slightly red or reddish-gray color; the residue of the ashes was nearly of the same tint, after a like treatment; and the soot gave a light drab or dirty white residuum. There appeared very little tendency in any of the specimens of clinker to vitrification, or the formation of coherent masses.

This coal ignites quickly and burns freely; it swells but little, and produces a coke moderately coherent.

Two trials on specimen b were made with the oxide of lead, resulting in giving for the first 27.870, and for the second 27.215 parts of lead reduced to one of coal employed.

Deducting 0.01397 for moisture, and 0.036 for ashes, the combustible is 0.95343; by which dividing the mean of the above two weights of lead, the result is 28.887.

The sample did not afford a sufficient quantity for trial either in the smith's fires, or in grates for domestic purposes.

·	Inches opening of damper	Upper 8.	

<sup>\*</sup> No period of steady action in combustion having been satisfactorily made out, owing to the smallness of the sample, the 11th and 12th deductions are necessarily omitted.

<sup>†</sup> The experiment was watched constantly until the valve was seated, and the level of water in the boiler adjusted at the moment the steam ceased to escape; hence no deduction for water to restore level is required.

<sup>‡</sup> This line cannot be filled, for reasons already stated.

No. 8.

Bituminous coal from Cannelton, Indiana, sent for trial by James Boyd, Esq., of Boston.

The following letter from the agent of Mr. Boyd accompanied one package of this sample of coal:

" Louisvil

"Sin: By direction of Mr. James Boyd, I have to-da by steamboat Orpheus, and via Wheeling, National re box of coal from Cannelton, Indiana. The object, as I by analysis the department may test its value as a fue

I send herewith the published character of the American Cannel Coal Company, in which you will find Dr. Jackson's analysis of the coal. Dr. F. Hall, of Washington, has recently examined the banks, &c., and has, I learn, expressed very favorable opinions of it in a letter to Francis Markoe, Esq., which will probably be published, and to which I would call your attention.

"From an experiment recently made on the steamer Messenger, (the results of which can be authenticated and forwarded, if desired,) I consider these facts as proven: that even on ordinary grate bars, this coal can be used without wood, and will generate steam more rapidly than the best ash or beach wood; that it does not injure the boilers as much, or the furnace more than wood. As to economy, safety, and convenience, &c., there can be no comparison.

"Very respectfully, your obedient servant,

"HAMILTON SMITH,

"One of the proprietors of the A. C. Coal: Company.
"The Hon. Secretary of the Navy, &c."

The exterior characters of this coal are a color deep black; a lustre shining, dull, or resinous, according as the main partings, the horizontal seams, or the cross cleats, are observed. The fracture is often conchoidal, and the lustre dull, like that of Scotch cannel coal. The main partings are at angles of 86° and 94° to the surfaces of deposition—such, at least, were the inclinations in several specimens which I measured. The aurfaces are frequently covered with films of sulphuret of iron. The powder, like that of most other highly bituminous coals, is distinctly brown; and the more so, the more minute the subdivision. Perfect anthracite is of a deep black, and pure bitumen is scarcely darker in color than burnt sienna. From these limits there is a gradual shading off towards the opposite extreme, according to the greater or less degree of bituminousness of the coal. The streak left on white earthenware is also distinctly brown; it has little or no tendency to soil when rubbed with the finger.

The specific gravity of one specimen of this sample (a) was 1.2479, that of another (b) 1.2975, and the mean of these affords the calculated weight per cubic foot 79.545 pounds; while 26 trials in the charge box gave the least weight 45.5, the greatest 55.25, and the average of the whole 47.649. This shows the actual weight to be 0.5986 of the calculated weight, from taking the specific gravity.

The moisture, in a pulverized specimen derived from 40 fragments, from different lumps of this sample, was 2.597 per cent; that of specimens a and

b was not separately ascertained. Twenty-eight pounds, dried in the steam apparatus, gave of moisture 0.893 per cent.

The volutile matter, including moisture, in  $\alpha$  was 38.157 by a moderate

rate of coking; and that in b, by the same treatment, 31.513.

Specimen a gave of rather heavy yellowish white ash, 3.498 per cent., and b of similarly colored residue 8.165. Hence the composition may, without material error, be assumed as follows, viz:

20.0						Specimen a.	Specimen $b$ .	
Moisture, from		cimens	- ,	-	•	2.597	2.597	
Other volatile m	atter	. •	• , `	-	-	<b>35.560</b>	28.916	
Earthy matter	•	-	•	•	· -	3.498	8.165	
Fixed carbon	••	-	•	-	•	58.345	60.322	
			•					
1						100.	100.	
Volatile	to fixed combustible		stible	•	- 1	:1.6407	1:2.086	

Of the above specimen of powder from 40 lumps of the coal, 71.48 grains gave of white ashes 2.73 grains = 3.819 per cent. Another portion of 68.87 grains, incinerated in a similar manner, gave 4.065 per cent. of ashes: the mean of these is 3.942.

Of the same powder, 124.17 grains exposed in a closely covered platinum crucible to a clear red heat till all flame had subsided, left of intumescent coke 78.75 grains. Hence the loss was 36.589 per cent.

. The composition deduced from this analysis may be stated as follows:

Moisture -	•	•	•		~	<b>—</b>	- 2.597
Other volatile m	natter	• •	-	. •	, •	1 -	- 33.992
Earthy matter	÷	••	-	-	-	•	- 3.942
Fixed carbon	-	- '	- \	-	-	•	- 59.469
	•		•				
			,				100.

Volatile to fixed combustible=1:1,7495.

During the experiments on evaporation, 2,465.5 pounds were consumed, leaving of—

Ashes	-	•	-	•	-	•	•	87.000	pounds.
Clinker	•	-	-	•	-	-	-	41.000	- 66
Soot	-	-	-	•	~	-	-	14.365	"
Of ma	tter	absolutely	inco	mbustible,	there	were in th	ıe		
Ashes		•	•	-	•	•		82.143	pounds.

JISNES .	-	•	-	-	•	•	-	82.143	pound
Clinker	-	•	-	•	-	•	• •	41.000	<b>~</b> 6
Soot	毋'	<b>-</b> ,	-	<b>-</b>	•	•	-	3.341	"
Total	•	•	•	•	•	•	- l	26.484	"
From w	hich	deduct w	ood as	nes -	•	-	•	0.997	"

And it leaves - - - - 125.487 pounds,

=4.9739 per cent. of the coal burned.

The clinker is in this case a mixture, in apparently equal quantities, of black vitreous porous portions, with light colored unvitrifiable shaly materials.

The whole is sufficiently friable to be easily broken, and shows no tendency to form continuous tenacious sheets. It was observed, however, in one instance, on clearing out the furnace, to adhere with considerable

force to the grate bars. It weighs 28.28 pounds per cubic foot; the ashes weigh 55.79, and the soot 3.29 pounds per cubic foot; the latter material being the lightest produced by any sample in the whole series. From the oxide of lead, specimen a of this coal reduced 24.91 times its weight, which, for one of combustible matter of the specimen, is 26.527.

I cannot offer an analysis by the organic method of any specimen from the Cannelton sample, but am enabled, through the kindness of the distinguished proprietor of an estate in the same coal field at Caseyville, Kentucky, to present the following result, which, so far as the constitution of the combustible matter is concerned, may be considered as affording a type of the Cannelton coal.

The specimen referred to had a specific gravity of 1.392,

By exposure to a temperature of 250° Fah., it lost 1.151 per cent. of its weight.

By rapid coking, the total loss is 37.96, and by slow coking 31.82 per cent.

Four incinerations (the results of which very nearly approached each other) gave the mean amount of earthy matter 23.6875 per cent. Hence the proximate ingredients were as follows:

Moisture	-	•	•	•	-	-	1.151
Other volatile	matte	r, (by s	low cok	ing)	-	-	30.669
Earthy matter	-	-	-	-	•	-	<b>23.687</b>
Fixed carbon	-	•	-	•			44,493
,					•	•	-
,							100.
		_				•	
Vola	tile to	fixed c	ombusti	ble	-	-	1:1.45

Of this coal, well dried, 4.21 grains (equal to 4.259 grains of the raw coal) were taken for analysis. This was treated in a combustion-tube with fused chromate of lead—a small portion of chlorate of potash being used to complete the combustion, and for that purpose placed near the bottom of the tube.

Having conducted the process with all the usual precautions, the analysis yielded 8.96 grains carbonic acid, and 1.92 grain water.

```
This gives carbon - - - 2.4436 grains.

hydrogen - - - 0.2133 "

2.6569 "
```

The ashes in 4.250 grains of the raw coal was - 1.0088 grain.

And the water - - - 0.0490 "

The total combustible matter was therefore 3.2012 grains; from which deducting 2.6569, the remainder (oxygen and azote) is 0.5443 grain.

The raw coal will, therefore, be composed of the following ingredients, viz:

Moisture -	•	•	= 1.151	
Carbon -	2.4436		(=57.375)	
Hydrogen -	.2133	+4.259	$\langle = 5.008 \rangle$	Combustible ingredients.
Oxygen and azote		<b>\</b>	(=12.779)	
Ashes -	•	-	=23.687	

As the fixed carbon by slow coking was 44.493, it appears that the portion of carbon volatilized was - 57.375—44.493—12.882 per cent.

hydrogen - - 5.008 oxygen and azote - - 12.779

Comparing together the combustible ingredients alone, there will be found in 100 parts of—

Carbon - - - 76.335=12.722 atoms.

Hydrogen - - 6.663= 6.663 "

Oxygen and azote - 17.002= 2.125 "

In order to verify the above, I analyzed another portion of the same powder, by means of the scale oxide of copper; using, however, more than double the quantity of coal previously employed.

8.87 grains of the dried coal (equal to 8.9733 grains of raw coal) were treated with that oxide recently recalcined and heated, and then placed with all care in a dry tube, and all moisture carefully exhausted.

The carbonic acid collected was - 18.66 grains.

Water - - 3.86 "

Hence the—

Garbon is - - - 5.0891 grains.

Hydrogen - - 0.4266 "

The moisture and ashes being deducted from the raw coal, leave 3.9733—2.2288 = 6.7445 of combustible matter; from which taking the carbon and hydrogen, there remains 1.2288 grain for oxygen and azote. From these data the following results are derived:

```
Moisture, as above - = 1.151

Carbon - - 5.0891 + 8.9733 = 56.714

Hydrogen - .4266 + 8.9739 = 4.754

Oxygen and azote - = 13.694

Ashes - - = 23.687
```

100.

Deducting, as before, moisture and ashes, the combustible ingredients are related to each other as follows:

Carbon - - 75.456=12.576 atoms.

Hydrogen - - 6.325= 6.325 "

Oxygen and azote - - 18.219= 2.252 "

I am disposed to attribute the slight superiority of hydrogen in the first over that in the second analysis to a trifling amount of moisture adhering to the chlorate of potash; for though this substance is generally regarded as anhydrous, I found, by exposure in a porcelain crucible to a temperature of 390°, at which it began to fuse, the loss was 0.82 per cent., as already stated in a former part of this report. Having, in a second experiment, with chromate of lead and chlorate of potash treated 12.32 grains of dried coal, I procured 5.29 grains of water, which makes the hydrogen 6.274 per cent. of the combustible matter; and in a fourth trial, in which the precipitated oxide of copper was employed, and the weight of dried coal was 6.38 graius, the proportion of hydrogen obtained was 6.596. Hence the following affords the result of these four trials:

1. With chromate of lead and undried chlorate	,		į	Tydrogen.	
of potash 2. With scale oxide of		grains of dried	coal gave	6.663 p	). c.
copper	8.87	46	"	6.325	"
3. With chromate and		•			
dried chlorate	12.32	<b>46</b>	"	6.274	"
4. With precipitated ox-					
ide of copper	6.38	66	66	6.596	66
Mean -			-	6.4645	' ''

I may mention that Richardson found the "parrot" coal of Edinburgh to possess 6.326 per cent. of hydrogen among its combustible ingredients, which agrees very nearly (that is, within the thousandth part of one per cent.) with my determination of the proportion in Caseyville coal, by means of the scale oxide of copper.

Assuming the mean of the above two determinations of the carbon, and that of the four trials for hydrogen, to represent truly the relation of those two constituents in the combustible matter of this coal, we have the means of computing the heating power of those elements, according to the principle hitherto adopted by chemists.

The combustible will consist of—

			•				100.
Oxygen and a	zote	•	-	-	•	,=	17.6405
Hydrogen -	-	-	•	•		-	6.4645
- u/ 00/6	-	•	-	-	•	-	75.8950

Deducting one-eighth of the weight of oxygen from that of the hydrogen, there remains 4.259.

Hence 0.04259 × 62535=2663=the heating power of the hydrogen; and 0.75895 × 12906=9795=the heating power of the carbon.

Reduced to steam-generating power, these numbers give-

2.585 lbs. of steam to 1 lb. of combustible, due to hydrogen, and 9.509 " " carbon.

Total 12.094

By reference to the table of experiments on gases drawn from the flues, it will be seen that two trials were made on the products of combustion from Cannelton coal, and that the mean heating power of one pound of coal (as the same was applied to all the four absorbents of that power) was 8.977 pounds of water generated from 212°. As the moisture and waste amounted to 6.013 per cent., the combustible is 0.93928 of the coal. Hence 8.977÷0.93928=9.557=the heating power of one of combustible, which, as in a preceding case, is almost identical with the above calculated steam-generating power of the carbon alone, independent of the hydrogen.

Trial was made of this coal in the chain and anchor shops. In the former, 60 pounds were found sufficient to put in only 5 links of a chain 11% inch in diameter. It produced a great blaze at first, but seemed soon to "go away into chaff," as expressed in the significant language of the workman employed in testing it. The coal of Atkinson & Templeman had put in of the same chain 8 links by 60 pounds; and the mean evaporative power

**[ 386 ]** 538

of that sample was 10.699 of water from 212°, while that of the Cannelton coal was 7.341. Now 10.699:7.341::8:5.4. This last is the number of links which the Cannelton coal ought to have made, had its heating power in the smith's forge been proportionate to its evaporative power. The two results agree within the fraction of four-nineteenths of a link. The true numbers of links would probably have been 80 and 54, had ten times as much coal been employed in each case.

In the anchor shop it proved very light, made a transient hot blaze, almost insupportable by the workmen; but as soon as that was gone, left

scarcely anything behind, and made no hollow fire.

In an office grate, a lump 15 inches in diameter was laid on a mass of ignited coke. It immediately took fire, and in three minutes was giving off a brilliant flame. From its flaky texture, it speedily disintegrated into flat masses, burning with little intumescence, and scarcely any tendency to agglutination. This property allows a free passage to the air, favors rapid combustion, and causes the exhibition of an exceedingly brilliant light. When the white flame had subsided, it was followed by one of a bright blue or purplish tint, (cyanogen?) which having subsided, left a light porous glowing coke, falling readily into small fragments, which preserve, to some extent, the original lamellated appearance of the coal. On the grate, under the steam boiler, it was observed to ignite readily; and it took only half an hour to bring the boiler into steady action, from the time the wood was withdrawn, and the charging with coal had commenced. No serious inconvenience was felt from the passage of fragments through the Its prompt and rapid action appears to adapt it, in a remarkable manner, to the purposes of Western steamboats. It seems to bear transportation better than any other sample of bituminous coal which came un-A large box which had come from the mines by steamboat, wagon, railroad ear, and drays, and had been subjected to five or six transhipments, contained scarcely any fine coal. Its very slight tendency to soil will also recommend it. The average quantity of unburnt coke left on the grate was but '63 pounds. This coal was received in three distinct packages, at as many different times; and there is reason to think that one part was taken from nearer the outcrop of the bed than the rest. This supposition is strengthened not only by the appearance of the coal, but by the difference in evaporative effects on the two trials, and the difference in amount of waste; the latter being one-fourth greater on the first trial than on the second. The average weight per cubic foot was more than 3.5 pounds (or upwards of 7 per cent.) less on the second than on the first trial.

The coal now under consideration was the only really available sample forwarded for trial from the great coal fields of the West. I may add, however, that two or three specimens were offered for analysis, besides

that received from Caseyville, already noticed.

A specimen from Wheeling, Virginia, had the following composition—its specific gravity being 1.2804:

The hygrometric moisture was
Other volatile matter - - - 42.626 "
Fixed carbon - - - 52.030 "
Earthy matter - - - 3.930 "

100.

The sulphur was 0.703 of one per cent.; the fixed to volatile combustible 1:1.22. The surfaces of deposition are covered with mineralized charcoal. The main partings are beautifully defined planes, inclined 85° to those of deposition. The cross partings are also pretty well defined, and exhibit a pitchy lustre. It is a rich coking coal, and will produce a large portion of highly illuminating gas.

A specimen from the Osage river, Missouri, had, in its dry state, a specific gravity less than 1, as it floated on water. When allowed to imbibe water, it sank, and was, when fully saturated, found to have a specific grav-

ity of 1.2. It contained of-

Moisture, expelle	ed at 23	0° -	•	•	- 1.67 per cent.
Other volatile ma	atter	-	•	•	- 41.83 "
Fixed carbon	-	•	•	•	- 51.16 "
Earthy matter	-	-	•	•	- 5.34 "
·					<del>- 7:0</del>
					100.
•					

A trial for sulphur gave 0.482 per cent of that material.

From the above analysis, the volatile is to the fixed combustible as 1:1.223. An analysis by the chromate of lead and the chlorate of potash, proved the combustible matter of this specimen to consist of—

Carbon -	-	-	-	- 81.855=13.642 atoms	i.
Hydrogen	•	•	-	- 6.168== 6.168 "	
Oxygen, &c.	-	•	•	- 11.977 <del>== 1.497 "</del>	
				<del></del>	
				100.	

From this analysis, the computation of evaporative power, assumed to be proportionate to the carbon, will give a result of 10.256 to 1 of combustible, and of 9.66 to 1 of the raw coal.

A specimen of pure bitumen, having a specific gravity of 1.1558, was found to contain of—

Volatile matter	-	•	: _	-	. •	-	72.439
Fixed carbon	-	-	-	•	•	•	24.799
Earthy matter	•	-	•	•	•	-	2.762
•							
•		•					100.

In this substance, therefore, the volatile is to the fixed combustible as 1:0.3423. Analyzed with the scale oxide of copper, 8.16 grains of this bitumen yielded 5.73 grains of water, and 22.6 grains of carbonic acid; from which is deduced the following composition of 100 parts of its combustible matter, viz:

•	•	•	•	- 77.679
•	•	-	•	- 8.023
•	-	•	•	- 14.298
				100.
	•	•		

The calculated evaporative power of the carbon in 1 of this combustible matter, is 9.464.

<b>6.8953</b>	,
<del></del>	Q;

Having completed the description of the fourth class of coals, I may here exhibit its relations to the series from Virginia. The synoptical table (page 551) will show that the average weight per cubic foot of eight samples of foreign and western coals is 49.31 pounds. The table already given of eleven samples of Virginia coals proves that they weighed 49.28 pounds. Eight foreign and western coals gave an average evaporative power of 7.984. Ten Virginia coals gave 8.477. Eight foreign and western, all burned with the chimney 63 feet high, evaporated on an average 13.778 cubic feet of water per hour. Six Virginia coals, burned with the same height of chimney, gave 13.73 cubic feet per hour. The lead reducing power of the combustible matter of the fourth class, compared with their evaporative power and with the ratios of fixed to volatile material, is seen in the following:

	Naı	me of co	al.			Steam to 1 of combustible.	Lead to 1 of combustible.	Fixed to 1 vol- atile matter.

No. 9.

### Experiment on dry pine wood.

During the progress of these experiments, there were used in heating up the boiler and its contents, with the brick work of the furnace, 25,367 pounds or 9 43 cords of dry yellow pine wood. This was of the ordinary kind, procured for use under the boilers which drive the engines in the navy yard.

It was brought to the apparatus from a pile kept in the open air, and consequently was dependent, in some degree, on the state of the weather for the quantity of moisture which adhered to it, and which caused a degree of diversity in the heating power it exhibited at different times.

It will be found, on computing the weight of wood required to raise the temperature of the boiler 1°, that this weight was generally the less, as the total range of temperature through which the boiler was heated was greater. It must evidently be so, because, in commencing many of the experiments, the temperature was either at or above 212°, and almost the whole heating power of the fuel was then expended in generating steam, or increasing the density of that already existing in the boiler. When, on the contract, the experiment commenced with the temperature of the water within the boiler 100° or more below the boiling point, a considerable proportion of the heat was expended in merely raising temperature. This subject will be made intelligible by the following short table, which has been drawn from the various tables of daily ob ervations on the amount of wood burned, as seen under the head of

"remarks," and from the corresponding ranges of temperature through which the water in the boiler was raised.

TABLE CLXXXVI.

Of the efficiency of pine wood in raising temperature.

Number of degrees through which the temperature was raised.	Number of pounds of wood required to each degree.	Number of degrees through which the temperature was raised.	Number of pounds of wood required to each degree.	Number of degrees through which the temperature was raised.	Number of pounds of wood required to each degree.
40	16.43 lbs.	280	6. 15 lbs.	64°	4.46 lbs.
	12.32	30	6.27	76	3 89
<b>6</b> 8	10.23	84	6.66	93	4 2 l 4.62
10	8.15	36	6.47	100	4.62
12	7.01	40	4 55	102	4 82
12 14	7.35	42	4.40	106	4.19
16	6.81	<b>44</b>	4.54	118	3.87
18	6.48	46	4.56	126	4 05
20	6.12	48	4.27	132	3.51
22	6.20	54	4.56	149	8.79
24	6.50	58	4.09	157	8.71
26	6.27	62	4.57	171	<b>3.</b> 86

The deviations from a regularly diminishing series of numbers, expressing the weights of wood for 1°, are doubtless caused in part by the fact that the wood was sometimes burned with the *lower* damper open, sometimes with the *upper*; and that occasionally the ash pit doors were open while burning wood, though closed as soon as the charging with coal commenced.

The heating with wood generally terminated at about 230°, or 18° above

the boiling point.

The wood on which the following experiment was made was formed into a pile 8 feet long and 4 feet high. It was stated by the engineer of the navy yard to be, both in quality and length of billets, a fair average of that generally in use at the yard.

In order to ascertain as nearly as possible the true cubical contents of the pile, every billet was measured by fixing a scale of inches in an upright position, and placing each billet against it with its lower extremity resting on the floor, and the shoulder of its upper axe-kerf brought against the scale. The portion which thus projected above the shoulder at one end was considered a just equivalent of what was taken away from the full size of the piece at the lower extremity.

In this manner the average length of the 201 pieces of which the pile: was composed, was found to be 42.134 inches, and the pile to contain 112 35 cubic feet. It weighed 2,360.5 pounds. Had it been composed of pieces 4 feet long, and constituted a true "cord of wood," its weight would have

been 2,689.2 pounds.

The charges were made to exceed as little as possible 100 pounds each. The temperature was, as usual, raised by burning a weighed quantity of wood; and, when it had reached its usual point, the unburnt portion was withdrawn, and a charge from the pile was substituted.

In the remarks appended to or following several of the tables of deductions, will be found some discussions of the influence of open air plates, as modified by other circumstances under which the experiments were conducted. The advantage to the 7 anthracites of using open air plates was, from the above table, on an average 0.43 per cent, to 19 free-burning coals, 2.18; to 10 Virginia coals, 1.86; and to 6 foreign and 1 western, 3.88 per cent.

TABLE CXCII.—Effect of open air plate on the rate of evaporation in the boiler when using different kinds of coal.

<sup>\*</sup> The two experiments with closed air plates were made before those with them open.

From the last column of the above table, it appears that the average diminution of activity or loss of useful effect in a given time by the boiler, was, for anthracites, 14.9 per cent.; for 3 free-burning coals, 2.63; for 5 Virginia coals, 1.48; and for 6 foreign and 1 western, 5.37 per cent.; making the average, for 31 kinds of coal, 5.37 per cent. A considerable positive gain, both in economy of fuel and in the time of the boiler, was effected, as appears from the above and the preceding table, by using the air plate open in the particular cases of the Karthaus, Creek Company's, Tipperanos, and Cannelton coals.

<sup>†</sup> The two experiments with open air plates were made before the other two, and while the outside of the boiler was more nearly free from soot than when using the closed plate.

#### TABLE CXCIII.

Observations on the time required by the products of combustion to pass from the grate to the chimney top, being a distance of 103.5 feet by the lower, and 168 by the upper damper passage, before the chimney was raised; and 125.5 by the lower, and 190 by the upper passage, after that addition.

# TABLE CXCIV-PART I-Continued.

	Deduct	Deductions relative to heating power of	e to heatir	Domer o	f finel.	
	Pounds of 1 lb. of parted to	steam from wate fuch, oquivalent		t, at 212°, to	avitatoga masta ai	Remarks.
Designation of coal.	L.—Escaping gasos.	-mon lo near WII fustion.	oirlymorgyH—.III .iis eth lo suisiem	Valor evapo- rated from boiler.	Total calculated ever to lot fuel, income \$12°.	[N. B.—In this table are presented all those experiments on the composition of the grass in which the series of observations was complete. In the daily rill be found some 25 or 30 other trials, in which only s were secretained; they serve to confirm, so far as to of these, in regard to the varying proportion of the lation while burning the same fuel.]
Beaver Meadow, slope No. 3 -	1.1012 0 8745 0.7931	0.17363	0.06336 0.05253 0.04455	9.5029 0.5429 8.9128	10.851 10.516 9.913	Dew point, at 95. 30m. a. m., by calculation, 71°.7; by observation, 71°.5. At 4½. 10m. p. m., dew point, by calculation, 72°.4; by observation, 72°.7. A heavier bed of coal on the grate than during the first drawing of gas. Dew point, at 8½. 30m. At 2½. 39m. p. m., by ' observation, 68°.7.
Forest Improvement	1.3800	0.71762	0.06388	10.0617 9.2064 10.3734	12.133 10.234 12.031	Tested for degen a second time, with same result. At 114, 30m. s. m., dev point, by observation, 74°, by calculation, 77°, 2. This result is probably too low, on account of the production of some carbonic oxide.
Peach Mountain	1.0035 0.9039 1.1864	0.12632 0.16130 0.24865	0.05751 0.05864 0.06784	10.2740 10.5780 10.2407	11.461	Fifty-soven cubic inches of gas in jar repeased through potass; no additional absorption.  A portion of gas in jar repeased through chloride of calcium and oxide of coppor: result allowed for in table.

### Remarks on the preceding table.

The last column shows that the lowest result from any given coal was generally obtained when the combustion was conducted with a damper partly closed. The want of a free access of air, the stifling effect of retaining the products of combustion near the fire, and the increased quantity of smoke produced in such cases, are sufficient indications of the source of this inferiority.

From the columns under "ratio to total bulk of dry gases, of carbonic acid and oxygen," it is found that the average per centage of those two materials, and their sum, for the several classes of coals, was as follows, viz:

٠ ()	1.)	Of the anthracite class by	22	analyses,	the	carb.	acid was	9.443;	oxygen,	12.094;	sum,	21.537
(:	2. j	Maryland free-burning	10	"			66	10.819	, 66	10.284	66	21.103

Ċ	7.)	Pine wood	· 2		3		66	9.214	66	10.213	"	19.437

In several of these cases, the sum of the oxygen and carbonic acid is almost identical with the proportion in which oxygen is found in the atmosphere. Thus, Nos. 2, 3, 4, and 5, give a mean of 10.315 of carbonic acid, 10.510 of oxygen. An excess may probably be referred, in some instances, to the existence of carbonic acid in the coal, in the state of carbonates; and a deficiency to the production of much water of combustion, as in cases of the highly bituminous coals and of pine wood.

The preceding table is derived from the numbers in the latter columns of table CXCIV, and gives the differences between the average total evaporative powers for each kind of coal found by the last column of that table, and the steam-generating power displayed by the boiler, as exhibited in the column immediately preceding.

### Heating power, as tested in making chains.

Nothing more than a very general approximation could be expected from this and similar methods of testing the relative strength of coals.

The same workman would not, probably, in every instance, make the

same number of links with the same number of pounds of coal.

A given coal, tried at two different periods, might, with a little more or a little less care and economy of time, give results considerably different from each other.

The relation, however, between the steam-generating and the chainmaking power of several of those coals between which considerable differences in constitution are known to exist, will be abundantly evident from inspection of the table.

Thus, between the Scotch and the Liverpool, and between the latter and the New York and Maryland Mining Company's, this relation becomes

apparent.

It will be seen that three different sizes of che manufacture at the different periods at which these They can, however, be all reduced to the same size a common standard sample of coal, which was use Thus, Atkinson & Templeman's coal made 18 in in diameter, and 8 links of another chain 11 inch in each case of 60 pounds of coal. Midlothian found adequate to the making of 14 links of 13-inc gima coals (viz: Crouch & Shead's, Creek Company's) having a mean evaporating with the Midlothian "new shaft," put in 9 links of

Admitting their heating power when tried on chain to be the same as that of the "new shaft;" then, in making chain 1 finch in diameter, they

would have been capable of making each 14 links of that size.

A decided general confirmation of the relative heating power of the coals, as deduced from evaporation, is afforded by the comparisons in the second and fifth columns of the following table. Thus—

Four samples, viz:	Scotch, Carnelton, Pictou, and Live-	Steam. 7.635	Links of chain.
Fige samples, viz-	Crouch & Spend's, Creek Company's,  Midlothian, (new shaft,) Chester- field, and Dauphin and Susquehanns,	8.769	14,49
Four samples, viz:	Newcastle, Blomburg, Quin's Run,	9.308	, <u>}641</u>
Four samples, viz:	Neff's, Atkinson & Templemen's, Barr's, and New York and Mary- land Mining Company,  gwe	9.871	19.00

For reasons above stated, and from the smallness of the quantity of goal used, the individual samples could hardly be expected to present fewer or less important discrepancies than are to be found in the table.

### TABLE CXCVI.

Relative heating powers of different bituminous couls, as tested in making chain cable, compared with their evaporative powers.

On the relative reductive powers of different classes of coals, as demonstrated by the experiments with exide of lead.

The general result of experiments on 37 varieties of coal, tested after the manner of M. Berthier, may be exhibited by collecting into one view the four average results derived from the several classes of coals. The mean ratio of fixed to volatile combustible matter of each class is added, affording the means of judging approximately how far the volatile constituent affects the reductive power. The weight of oxygen given up by the lead, reduced by 1 part of combustible matter in the coal assayed, is calculated from the known composition of litharge. Had the combustible matter been pure carbon, and the product only carbonic acid, the oxygen would have been 2.66 parts to 1 of combustible. This, it will be seen, is only approached by the anthracipes, and is farther and farther receded from by the bituminous coals, in proportion as their bituminousness increases. To the series of averages of my own experiments, I annex a similar series of the results given by M. Baudin, some of which have already been separately cited.

### TABLE OXCVII.

Average reductive powers of American and foreign coals, as tested by litharge.

The French anthracites had obviously a much larger proportion of volatile matter than the American. They correspond in this respect very nearly with the natural coke of Virginia, of which the ratio of fixed to volatile combustible is 6.269. The average result in lead obtained by M. Baudin for the four classes of coals is about 2.2 per cent. higher than that given by my trials of analogous classes. This I attribute to a probable slight admixture of red oxide with the protoxide of lead which I employed. Though procured from a house of high calebrity for dealing in pure chemicals, its complexion led to the suspicion of a slight excess of oxygen in its composition. As, however, the same kind of litharge was used for all the samples of coal, the purpose of these comparative trials is equally well answered as if it had been chemically pure.

In some of the ultimate analyses of coals stready reported may be found evidences, that the lead-reducing power depends (as the foregoing table indicates) on the carbon constituent, and not on the other elements. Thus the analysis of Cambria county coal of Pennsylvania proved its combustible matter to contain 91.955 per cent. of carbon, and experiment showed its lead-reducing power to be 31.464. Again, ultimate analysis showed Clover Hill coal of Virginia to have in its combustible matter 83.393 per cent. of carbon, and the trial by litharge proved the reductive power of the same combustible matter to be 28.527. Now, to compute the reductive power of Clover Hill combustible matter from its carbon, we have

597 [ 386 ]

The tables last presented, containing, first, a general synoptical view of the character and efficiency of the several coals, and, secondly, a number of distinct classifications in reference to different characters considered to be of the most practical importance, and based, in every instance, on the numerical results of experiment, will, I trust, be found highly serviceable in guiding those whose duty it may be to make choice of fuel for the naval or other public service, to the selection of such as will answer the specific object for which they may be procured.

In applying the table of ranks, it will readily be understood that, where any given rank is determined by a series of numbers (on the right of the names) increasing downwards, the number at the top is used as a dividend, to be divided by each of those below it; and that, on the contrary, where the rank is decided by a series diminishing downwards, the number at the top becomes a divisor for each of those below it: and in both cases, the quotients become series of decimals, expressive of the relative values of the coals against which they stand, as compared with that occupying the head of the list taken as unity.

If an equal importance could be attached to every one of the qualities of coals which form the bases of the ten ranks above given, then the sum of the ratios or relative values found in the last columns would, for any sample, give nearly its true relative value in the market. Such equality does not, however, exist. Nor is it easy to assign the exact relative weight or importance of the several qualities indicated. For different purposes they must be differently estimated. Thus, when sold by weight and used on shore, the weight per cubic foot, as given in the first rank, is a point of little moment. Space for stowage is easily obtained. But in steam navigation, bulk, as well as weight, demand attention; and a difference of twenty per cent., which experiment shows to exist between the highest and the lowest average weight of a cubic foot of different coals, assumes a value of no little magnitude.

For the purposes of steam navigation, therefore, the rank most important to be considered is the fifth, in which the names of coals stand in the order of their evaporative power, under given bulks. This is obviously true, since, if other things be equal, the length of a voyage must depend on the amount of evaporative power afforded by the fuel which can be stowed in the bunkers of a steamer, always of limited capacity.

With the scale of values under equal bulks must, however, be combined those in the eighth and tenth ranks, the former showing the relative freedom from clinker, and the latter the maximum rapidity of action of the several samples. The rapidity of ignition, given in the second rank, is of inferior importance, but may deserve some consideration where short voyages, frequent stoppages, and a prompt commencement of action, are demanded.

In relation to the 10th rank—that founded on maximum rapidity of evaporation—it should be observed, that, though in this, as in all other cases, the actually observed rate of action is inserted in the table, yet that the few samples which were in every experiment burned with a chimney only 41 feet high, instead of 63 feet, (which was its height after the 27th of May,) ought to have the numbers showing the evaporation per hour in cubic feet increased nearly in proportion to the increased height of chimney. Samples numbered 32, 35, 39, 40, and 41, in that rank, are those to which this remark more particularly applies.

[ 386 ] 598

As every sample of coal has been allowed a fair opportunity to exhibit its own distinctive character, it would be useless to attempt to substitute for the results of practical experiments, on such a scale as is here presented, any mere opinions or conjectures derived from observations made at random, with no standards of time, weight, or magnitude; or even any theoretical conclusions drawn from tests, however skilfully applied, merely to single hand specimens. It has been my aim in all these researches to avoid matters extraneous to the experiments themselves and to their legitimate interpretation. It has not been deemed expedient to swell this report by the introduction of matters not within my own cognizance.\*

The numerous certificates and declarations which, either in the form of reports, or other published articles, have from time to time been put forth in regard to certain coals, may in some instances be entitled to consideration, as evidences of their superior worth; in others, of a commendable industry and energy on the part of the proprietors, agents, directors of companies, and others interested in their development and use. If these commendations have not in every instance been entirely justified, it is perhaps to be taken as a new evidence that in this, as in many other important matters, those merits which have not been the most loudly proclaimed may, upon due examination, be found among the most estimable and the most

enduring,

It will not fail to be remarked, that the justly celebrated foreign bituminous coals of Newcastle, Liverpool, Scotland, Pictou, and Sidney—coals which constitute the present reliance of the great lines of Atlantic steamers—are fully equalled, or rather surpassed in strength, by the analogous coals of eastern Virginia; that they are decidedly surpassed by all the free-burning coals of Maryland and Pennsylvania; and that an equally decided advantage in steam-generating power is enjoyed by the anthracites over the foreign coals tried, whether we consider them under equal weights or equal bulks.

Experiment appears to demonstrate that, for the purposes of rapid evaporation, and for the production of illuminating gas, the coal of Indiana, though neither very heavy nor very durable, is inferior to none of the highly bituminous class to which it belongs; since in heating power, and in freedom from impurity, it surpasses the splint and cannel coal of Scotland.

Apprized of the strong desire felt by the department to be in possession of the results of these inquiries, I have spared no effort to bring them to an early conclusion, though satisfied that in doing so the researches cannot be

considered complete.

One of the important points which it would be desirable further to investigate, is the proportion of sulphur; which, it will be seen by the several synoptical tables, was only tested on single specimens, for a part of the series. This is a labor of time, which, for reasons already assigned, is unavoidably left incomplete.

Another point of practical importance is the composition of the earthy matter, or ashes, of each coal. On the investigation of this, it was not found practicable even to enter. It is of no inconsiderable interest, in relation to

<sup>\*</sup> For an account of numerous results obtained by Dr. Dana, Mr. Francis, Mr. Hayes, and others, in relation to this subject, by means analogous to those which have been here employed, I would respectfully refer to a paper on the evaporative power of coals in the second Bulletin of the National Institute, (February, 1842,) page 165.

on this subject upon the samples of coal here reported, I beg leave to add a series of analyses of this nature, which I made some years since. They are chiefly the ashes of anthracites. One happens, however, to have come from the same mines which furnished one of the samples of bituminous coal examined in this report.

TABLE CCII.

Composition and character of ashes from several varieties of coal.

Characters and ingredients of ashes.	Sugarloaf Company's anthracite, Hasle creek-lst specimen. Specific gravity 1.591.	Sugarloaf anthracite—2d specimen. Specific gravity 1.574. I cannot by any means regard the investigation of American coals as an exhausted subject.

A glance at any good geological map of the United States, in which the coal fields are laid down, will show how exceedingly limited is the whole amount of space covered by the several detached coal troughs from which the samples here presented were derived, compaled with the immense extent of that formation which covers western Pennsylvania and Virginia, eastern Ohio, the eastern part of Kentucky, a part of middle Tennessee, and an undefined portion of Alabama; and much more when compared with the vast tracts of coal country in Illinois, Iowa, Missouri, Arkansas, and a considerable portion of Michigan.

The surprising extension of steam navigation on the western rivers and the northwestern lakes, as well as on the gulf of Mexico and the adjacent seas, the increase of population, and the consequent clearing of woodlands,

all point significantly to a necessity which must be felt, at no distant day, to have recourse to mineral fuel for supplying this rapidly increasing demand.

To understand the relative strength and usefulness of the coals from the several parts of the three great western coal regions, requires that they be examined with no less care than has been applied to the limited spaces from which were derived the materials operated on during these experiments. It may be added, that the products of many coal districts east of the Allegany mountains are yet unexamined.

If in any case knowledge is power, it is pre-eminently so when it relates to a subject which constitutes the greatest element of power in the physical

world, and in the present age of marvellous developments.

I cannot conclude this report without again bearing testimony to the efficient aid which the industry and intelligence of my principal assistant and co-laborator, Dr. Henry King, has rendered in carrying out my views in the arrangement and computation of many of the tables accompanying this report. To his perseverance, with that of another assistant, Mr. S. W. Hall, do I owe the application of the formulas which I had prepared for ascertaining the mean pressures of steam during every day's experimenting, and also of those for computing the table of experiments on the composition and heat-absorbing powers of the gases of the chimney. The labor of these and similar computations, even with all the aid which mathematical tables afford, is exceedingly arduous, and requires the utmost vigilance to avoid error. It is, perhaps, too much to hope that no inaccuracy whatever has occurred in their applications of these formulas, embracing, as they necessarily do, numerous classes of elements. But as every examiner of the work will have all the data before him, mere numerical errors, should such occur, can be readily discovered and corrected.\*

In the hope that the results now offered for your acceptance will be found serviceable to the important arm of national defences committed to your charge, and to justify the favorable views of the enlightened and lamented statesmant under whose immediate anspices they were commenced, I have now the honor to submit them to your hands, with the assurance that I

remain, with great respect, your obedient servant,

WALTER R. JOHNSON.

Washington, June 3, 1844.

It is due to two other assistants to state that the records of nearly all the observations on evaporative power were made by Mr. James W. Kendall, by whom also much aid was rendered in preparing the tables, and making the calculations necessary to form the deductions accompanying this report; and that the duties of superintending the supply of water during the experiments, the drying of samples of coal, of making observations on the temperature of water in the supplying reservoir, and of steam in the boiler, were committed to Captain Thomas S. Easton. The duties of both these assistants were performed with a zeal, constancy, and fidelity, meriting high approbation.

† The late Hon. Abel P. Upshur, then Secretary of the Navy.

## INDEX.

For convenient reference to the numerous samples of coal, to the distinct points of inquiry, to the various descriptions of apparatus, to the several modes of experimenting, and to the different classes of results, an index to this report has been deemed indispensable, and is herewith furnished.
